s13x_nrf5x_7.2.0 migration document

Introduction to the s13x_nrf5x migration document

About the document

This document describes how to migrate to new versions of the s130_nrf51 and s132_nrf52 SoftDevices. The s130_nrf51 and s132_nrf52 release notes should be read in conjunction with this document.

For each version, we have the following sections:

- "Required changes" describes the changes that need to be done in the application when migrating from an older version of the SoftDevice.
- "New functionality" describes how to use new features and functionality offered by this version of the SoftDevice. Note: Not all new functionality may be covered; the release notes will contain a full list of new features and functionality.

Each section describes how to migrate to a given version from the previous version. If you are migrating to the current version from the previous version, follow the instructions in that section. To migrate between versions that are more than one version apart, follow the migration steps for all intermediate versions in order.

Example: To migrate from version 5.0.0 to version 5.2.0, first follow the instructions to migrate to version 5.1.0 from version 5.0.0, then follow the instructions to migrate to version 5.1.0.

s132_nrf52_7.2.0

This section describes how to use the new features of s132_nrf52_7.2.0 when migrating from s132_nrf52_7.0.1. As with all minor releases, the s132_nrf52_7.2.0 is binary compatible with s132_nrf52_7.0.1.

New functionality

Efficient discovery of 128-bit UUIDs

By default, any discovered 128-bit UUIDs that are not present in the Vendor Specific UUID table, will have the ble_uuid_t::type set to BLE_UUID_TYPE_UNKNOWN.

To change this default behavior and enable the automatic insertion of discovered 128-bit UUIDs to the Vendor Specific UUID table, the following option can be used:

sd_ble_opt_set(BLE_GATTC_OPT_UUID_DISC, &(ble_opt_t){.gattc_opt.uuid_disc.auto_add_vs_enable = 1});

s132_nrf52_7.0.1

This section describes how to use the new features of s132_nrf52_8.0.0 when migrating from s132_nrf52_7.0.1. Due to API changes between these versions, applications have to be to be recompiled.

Required changes

The application can no longer use the option BLE_COMMON_OPT_ADV_SCHED_CFG. The advertiser will always use improved scheduling. This was previously defined as ADV_SCHED_CFG_IMPROVED.

The macros NRF_SOC_APP_PPI_CHANNELS_SD_DISABLED_MSK, NRF_SOC_APP_PPI_CHANNELS_SD_ENABLED_MSK, NRF_SOC_APP_PPI_GROUPS_SD_DISABLED_MSK, and NRF_SOC_APP_PPI_GROUPS_SD_ENABLED_MSK are removed. The application can use the macros NRF_SOC_SD_PPI_CHANNELS_SD_ENABLED_MSK and NRF_SOC_SD_PPI_GROUPS_SD_ENABLED_MSK to deduce the PPI channels and groups available to the application.

New functionality

Connection event trigger

When enabled, this feature will trigger a task at the start of connection events. The application can configure the SoftDevice to trigger a task every N connection events starting from a given connection event counter.

API Updates

- sd_ble_gap_next_conn_evt_counter_get(). This API can be used to retrieve the next connection event counter.
- sd_ble_gap_conn_evt_trigger_start(), sd_ble_gap_conn_evt_trigger_stop(). These APIs can be used to start and stop triggering a task on connection events.

Usage

The code snippet below illustrates how to configure the SoftDevice to toggle the GPIO pin 13, every second connection event, starting at connection event 10. The code snippet stops the connection event trigger when the connection parameters are updated.

```
void on_ble_evt(const ble_evt_t * p_ble_evt)
{
    if (p_ble_evt->header.evt_id == BLE_GAP_EVT_CONNECTED)
    {
        uint16_t conn_handle = p_ble_evt->evt.gap_evt.conn_handle;
    }
}
```

```
ble_gap_conn_event_trigger_t trigger_params;
    trigger params.ppi ch id = 0;
    trigger_params.task_endpoint = &NRF_GPIOTE->TASKS_OUT[0];
    trigger_params.conn_evt_counter_start = 10;
    trigger params.period in events = 2;
    sd_ble_gap_conn_evt_trigger_start(conn_handle, &trigger_params);
  }
  else if (p_ble_evt->header.evt_id == BLE_GAP_EVT_CONN_PARAM_UPDATE)
    uint16 t conn handle = p ble evt->evt.gap evt.conn handle;
    sd_ble_gap_conn_evt_trigger_stop(conn_handle);
  }
ł
int main(void)
  /* Configure GPIOTE */
 NRF GPIO->DIRSET = (1 << 13);</pre>
 NRF GPIOTE->CONFIG[0] = (GPIOTE CONFIG POLARITY Togqle << GPIOTE CONFIG POLARITY Pos)
                            (13 << GPIOTE_CONFIG_PSEL_Pos)</pre>
                            (GPIOTE CONFIG MODE Task << GPIOTE CONFIG MODE Pos);
 /* Enable the BLE Stack and connect device */
 sd_ble_enable(...);
  sd_ble_gap_connect(...);
  [...]
ļ
```

Configurable inclusion of Central Address Resolution (CAR) characteristic and Peripheral Preferred Connection Parameters (PPCP)

API Updates

- BLE_GAP_CFG_CAR_INCL_CONFIG. This allows the application to include or exclude the CAR characteristic from the GAP Service.
- BLE_GAP_CFG_PPCP_INCL_CONFIG. This allows the application to include or exclude the PPCP characteristic from the GAP Service.

For the above inclusion configuration APIs, the application can use:

- BLE_GAP_CHAR_INCL_CONFIG_INCLUDE: The characteristic is included.
- BLE_GAP_CHAR_INCL_CONFIG_EXCLUDE_WITH_SPACE: The characteristic is excluded, but the SoftDevice will reserve the attribute handles which are otherwise used for this characteristic.
- BLE_GAP_CHAR_INCL_CONFIG_EXCLUDE_WITHOUT_SPACE: The characteristic is excluded.

When CAR is excluded and the SoftDevice is configured to support the central role:

- It is not possible to distribute own IRK.
- It is not possible to enable privacy.

Usage

The code snippet below illustrates how to configure the SoftDevice to exclude both CAR and PPCP from the GAP Service.

```
int main(void)
{
    ble_cfg_t cfg;
    /* Exclude CAR from GAP service, but reserve the ATT Handles that will otherwise be used up by CAR. */
    cfg.gap_cfg.car_include_cfg = BLE_GAP_CHAR_INCL_CONFIG_EXCLUDE_WITH_SPACE;
    sd_ble_cfg_set(BLE_GAP_CFG_CAR_INCL_CONFIG, &cfg, ..);
    /* Exclude PPCP from GAP service, but reserve the ATT Handles that will otherwise be used up by PPCP. */
    cfg.gap_cfg.ppcp_include_cfg= BLE_GAP_CHAR_INCL_CONFIG_EXCLUDE_WITH_SPACE;
    sd_ble_cfg_set(BLE_GAP_CFG_PPCP_INCL_CONFIG, &cfg, ..);
    /* Enable the BLE Stack. */
    sd_ble_enable(...);
    [...]
}
```

s132_nrf52_6.1.0

This section describes how to use the new features of s132_nrf52_6.1.0 when migrating from s132_nrf52_6.0.0. As with all minor releases, the s132_nrf52_6.1.0 is binary compatible with s132_nrf52_6.0.0. Hence existing applications running on s132_nrf52_6.0.0 need not be recompiled unless the new features are needed. Advertising extensions are now fully tested and qualified features.

New functionality

Support for advertising with up to 255 bytes of advertising data

The SoftDevice now supports advertising up to 255 bytes of advertising data. The macro BLE_GAP_ADV_SET_DATA_SIZE_EXTENDED_MAX_SUPPORTED is added to indicate this. For connectable extended advertising, the maximum advertising data size is 238 bytes, as indicated by BLE_GAP_ADV_SET_DATA_SIZE_EXTENDED_CONNECTABLE_MAX_SUPPORTED.

```
.properties=
     .type=BLE_GAP_ADV_TYPE_EXTENDED_NONCONNECTABLE_NONSCANNABLE_UNDIRECTED
    },
    .interval
                          = BLE GAP ADV INTERVAL MAX,
                          = BLE_GAP_ADV_TIMEOUT_LIMITED_MAX,
    .duration
    .channel mask
                          = \{0\},
    .max_adv_evts
                          = 0,
    .filter_policy
                         = BLE_GAP_ADV_FP_ANY,
    .primary_phy
                        = BLE_GAP_PHY_1MBPS,
    .secondary phy
                        = BLE_GAP_PHY_2MBPS,
  };
/* Enable the BLE Stack */
sd_ble_enable(...);
[...]
sd_ble_gap_adv_set_configure(&adv_handle, &adv_data, &adv_params);
/* Start advertising */
sd_ble_gap_adv_start(adv_handle, BLE_CONN_CFG_TAG_DEFAULT);
[...]
```

Extended Scannable Advertising with 255 bytes of Scan Response data

```
.scan_rsp_data.p_data = raw_scan_rsp_data_buffer,
     .scan_rsp_data.len = sizeof(raw_scan_rsp_data_buffer)
    };
int main(void)
  uint8_t adv_handle = BLE_GAP_ADV_SET_HANDLE_NOT_SET;
 ble_gap_adv_params_t adv_params =
     .properties=
      .type=BLE_GAP_ADV_TYPE_EXTENDED_NONCONNECTABLE_SCANNABLE_UNDIRECTED
     },
     .interval
                      = BLE_GAP_ADV_INTERVAL_MAX,
                        = BLE_GAP_ADV_TIMEOUT_LIMITED_MAX,
     .duration
     .channel_mask
                           = \{0\},
     .max_adv_evts
                            = 0,
    .filter_policy = BLE_GAP_ADV_FP_ANY,
.primary_phy = BLE_GAP_PHY_1MBPS,
     .secondary phy = BLE GAP PHY 2MBPS,
    };
  /* Enable the BLE Stack */
  sd_ble_enable(...);
 [...]
  sd_ble_gap_adv_set_configure(&adv_handle, &adv_data, &adv_params);
  /* Start advertising */
  sd ble qap adv start(adv handle, BLE CONN CFG TAG DEFAULT);
  [...]
```

Support for receiving up to 255 bytes of advertising data

The SoftDevice now supports receiving up to 255 bytes of advertising data as a scanner. The macro BLE_GAP_SCAN_BUFFER_EXTENDED_MAX_SUPPORTED is added to indicate this.

```
static uint8 t raw scan buffer[BLE GAP SCAN BUFFER EXTENDED MAX SUPPORTED];
static ble data t scan buffer =
   {
     .p_data = raw_scan_buffer,
    .len = sizeof(raw_scan_buffer)
   };
static uint16_t scan_window = 0x00A0; /* Corresponds to 100 ms */
int main(void)
 ble gap scan params t scan params=
     .extended = 1, /* Enable extended scanning to be able to receive large advertising data. */
     .scan phys = BLE GAP PHY 1MBPS,
    .timeout = BLE_GAP_SCAN_TIMEOUT_UNLIMITED,
    .window = scan_window,
     .interval
                 = BLE GAP SCAN INTERVAL MAX,
    .channel_mask = \{0\}, /* Scanning on all the primary channels */
    .filter policy = BLE GAP SCAN FP ACCEPT ALL
   };
  /* Enable the BLE Stack */
  sd_ble_enable(...);
  /* Start scanning */
  sd_ble_gap_scan_start(&scan_params, &scan_buffer);
 [...]
```

API for removing a Vendor Specific base UUID

Using sd_ble_uuid_vs_remove(), the application can now remove a Vendor Specific base UUID that has been added with sd_ble_uuid_vs_add(). This allows the application to reuse memory allocated for Vendor Specific base UUIDs. The application must provide a pointer to the UUID type to be removed as an input parameter to sd_ble_uuid_vs_remove(). The UUID type must not be in use by the ATT Server. A limitation with the current implementation is that the input parameter can only point to BLE_UUID_TYPE_UNKNOWN or the last added UUID type.

API to enable or disable extended RC calibration

Extended RC calibration is a new SoftDevice feature that performs additional RC oscillator drift detection and calibration when the SoftDevice is acting as a peripheral and the RC oscillator is used as the SoftDevice clock source. The extended RC calibration is performed in addition to the periodic calibration which is configured when calling sd_softdevice_enable(). If using only peripheral connections, the periodic calibration can then be configured with a much longer interval because the peripheral can detect and adjust automatically to clock drift and calibrate when required.

The extended RC calibration is enabled by default. The option BLE_COMMON_OPT_EXTENDED_RC_CAL is added to the BLE option API, allowing the application to enable or disable this feature. When using this API, set ble_common_opt_t::extended_rc_cal::enable to '1' to enable, or to '0' to disable.

API to get the advertiser Bluetooth device address

A new API sd_ble_gap_adv_addr_get() enables the application to get the local Bluetooth device address that is used by the advertiser. The application must provide the advertising handle of the advertiser for the adv_handle input parameter, and a pointer to an address structure p_addr to be used as the output parameter. The function may only be called when advertising is enabled.

Note: If privacy is enabled, the SoftDevice will generate a new private address every ble_gap_privacy_params_t::private_addr_cycle_s, which is configured when calling sd_ble_gap_privacy_se t(). Depending on when sd_ble_gap_adv_addr_get() is called, the returned address may not be the address that is currently used by the advertiser.

Hardware resource usage API

The API now contains new macros to inform the application about the hardware resources used by the SoftDevice.

- The macro __NRF_NVIC_SD_IRQ_PRIOS indicates the interrupt priority levels used by the SoftDevice.
- The macro __NRF_NVIC_APP_IRQ_PRIOS indicates the interrupt priority levels available to the application.
- The macros NRF_SOC_SD_PPI_CHANNELS_SD_ENABLED_MSK and NRF_SOC_SD_PPI_CHANNELS_SD_DISABLED_MSK can be used to identify the PPI channels reserved by the SoftDevice when the SoftDevice is enabled or disabled respectively.
- The macros NRF_SOC_APP_PPI_CHANNELS_SD_ENABLED_MSK and NRF_SOC_APP_PPI_CHANNELS_SD_DISABLED_MSK can be used to identify the PPI channels available to the application when the SoftDevice is enabled or disabled respectively.
- The macros NRF_SOC_SD_PPI_GROUPS_SD_ENABLED_MSK and NRF_SOC_SD_PPI_GROUPS_SD_DISABLED_MSK can be used to identify the PPI groups reserved by the SoftDevice when the SoftDevice is enabled or disabled respectively.
- The macros NRF_SOC_APP_PPI_GROUPS_SD_ENABLED_MSK and NRF_SOC_APP_PPI_GROUPS_SD_DISABLED_MSK can be used to identify the PPI groups available to the application when the SoftDevice is enabled or disabled respectively.

Other additions to the API

- The macro SD_VARIANT_ID indicates the SoftDevice variant.
- The macro SD_FLASH_SIZE indicates the amount of flash memory used by the SoftDevice.

s132_nrf52_6.0.0

This section describes how to migrate to s132_nrf52_6.0.0 from s132_nrf52_5.1.0.

Notes:

- s132_nrf52_6.0.0 has changed the API compared to s132_nrf52_5.1.0 which requires applications to be recompiled.
- s132_nrf52_6.0.0 includes some features that are not Bluetooth qualified. For more information, see the release notes.

New functionality

Quality of Service (QoS) channel survey

This feature provides measurements of the energy levels on the Bluetooth Low Energy channels to the application. The application can use this information to determine the noise floor on a per channel basis and set an adapted channel map to avoid busy channels.

Note: To make the channel survey feature available to the application, ble_gap_cfg_role_count_t::qos_channel_survey_role_available must be set. This is done using the sd_ble_cfg_set() A PI.

The event structures for BLE_GAP_EVT_RSSI_CHANGED and BLE_GAP_EVT_ADV_REPORT have been changed to provide the application the channel number for reported Received Signal Strength Indication (RSSI) measurements. For more information, see Updated RSSI API in the Required changes section.

API Updates

• A new Boolean flag, ble_gap_cfg_role_count_t::qos_channel_survey_role_available, must be set in the SoftDevice role configuration API to make the channel survey available for the application.

- Two new SV calls have been added to start and stop the channel survey:
 - sd_ble_gap_qos_channel_survey_start()
 - sd_ble_gap_qos_channel_survey_stop()

```
/* Make Channel Survey feature available to the application */
ble_cfg_t cfg;
cfg.role_count.qos_channel_survey_role_available = 1;
sd ble cfg set(..., &cfg, ...);
```

```
/* Start receiving channel survey continuously. */
uint32_t errcode;
errcode = sd_ble_gap_qos_channel_survey_start(BLE_GAP_QOS_CHANNEL_SURVEY_INTERVAL_CONTINUOUS);
```

```
int8_t rssi;
/* A new measurement is ready. */
case BLE_GAP_EVT_QOS_CHANNEL_SURVEY_REPORT:
{
    for (i = 0; i < BLE_GAP_CHANNEL_COUNT; i++)
    {
        rssi = p_ble_evt->evt.gap_evt.params.qos_channel_survey_report.channel_energy[i];
    }
}
```

```
/* Stop receiving channel survey. */
errcode = sd_ble_gap_qos_channel_survey_stop()
```

Advertising Extensions

The LE Advertising Extensions feature has limited support in this SoftDevice that can be enabled with the new advertiser and scanner API. The feature may not function as specified, and may contain issues. For more information, see the release notes.

Extended Advertiser

Extended advertising can be enabled by assigning an _EXTENDED_ advertising type to the ble_gap_adv_params_t::properties::type.

The extended advertising types are:

BLE_GAP_ADV_TYPE_EXTENDED_CONNECTABLE_NONSCANNABLE_UNDIRECTED BLE_GAP_ADV_TYPE_EXTENDED_CONNECTABLE_NONSCANNABLE_DIRECTED BLE_GAP_ADV_TYPE_EXTENDED_NONCONNECTABLE_SCANNABLE_UNDIRECTED BLE_GAP_ADV_TYPE_EXTENDED_NONCONNECTABLE_SCANNABLE_DIRECTED BLE_GAP_ADV_TYPE_EXTENDED_NONCONNECTABLE_NONSCANNABLE_UNDIRECTED BLE_GAP_ADV_TYPE_EXTENDED_NONCONNECTABLE_NONSCANNABLE_DIRECTED

New parameters in the API that are relevant for extended advertising:

- ble_gap_adv_params_t::properties::anonymous
 - If this flag is set to 1, the advertiser's address will be omitted from all PDUs. This is only available for extended advertising event types.
- ble_gap_adv_params_t::primary_phy
 - Indicates the PHY on which the primary advertising channel packets are transmitted.
 - For extended advertising event types, this can be set to BLE_GAP_PHY_AUTO, BLE_GAP_PHY_1MBIT, or BLE_GAP_PHY_CODED if supported by the SoftDevice.
- ble_gap_adv_params_t::secondary_phy
 - Indicates the PHY on which the auxiliary PDUs will be sent.
 - Can be set to BLE_GAP_PHY_AUTO, BLE_GAP_PHY_1MBPS, BLE_GAP_PHY_2MBPS, or BLE_GAP_PHY_CODED if supported by the SoftDevice.
- ble_gap_adv_params_t::set_id
 - This value is used as the Advertising Set ID in the AdvDataInfo field of the PDU.

Extended Scanner

Scanning of extended advertising PDUs can be enabled by setting the ble_gap_scan_params_t::extended flag to 1 for the scan parameters provided to sd_ble_gap_scan_start(). If set to 1, both legacy and extended advertising PDUs will be scanned. If the flag is set to 0, all extended advertising PDUs will be ignored by the scanner. Correspondingly, to connect to a peer that is advertising with extended advertising PDUs, set the ble_gap_scan_params_t::extended flag to 1 for the scan parameters provided to sd_ble_gap_connect().

New parameters in the API that are relevant for extended scanning:

- ble_gap_scan_params_t::report_incomplete_evts
 - This option is currently not supported.
- ble_gap_evt_adv_report_t::type::extended_pdu
 - Will be set to 1 if an extended advertising set is received.
- ble_gap_evt_adv_report_t::tx_power
 - The transmit power reported by the advertising in the last packet header received. The TX power field is present only in some extended advertising PDUs.
- ble_gap_evt_adv_report_t::aux_pointer
 - The offset and PHY of the next advertising packet in this extended advertising set.
 - This field will only be set if ble_gap_evt_adv_report_t::type::status is set to BLE_GAP_ADV_DATA_STATUS_INCOMPLETE_MORE_DATA.
- ble_gap_evt_adv_report_t::set_id
 - Set ID of the received advertising data. This is only present in some extended advertising PDUs.
- ble_gap_evt_adv_report_t::data_id
 - Data ID of the received advertising data. This is only present in some extended advertising PDUs.

Write to SoftDevice protected registers

A new API, sd_protected_register_write(), has been added to give the application the possibility to write to a register that is write-protected by the SoftDevice. A write-protected peripheral shall only be accessed through the SoftDevice API when the SoftDevice is enabled.

The new API supports writing to the Block Protection (BPROT) peripheral. The application can use sd_protected_register_write() instead of sd_flash_protect() to set the flash protection configuration registers.

```
/* Old API: */
errcode = sd_flash_protect(value0, value1, value2, value3)
```

```
/* New API: */
errcode = sd_protected_register_write(&(NRF_BPROT->CONFIG0), value0)
```

```
errcode = sd_protected_register_write(&(NRF_BPROT->CONFIG1), value1)
errcode = sd_protected_register_write(&(NRF_BPROT->CONFIG2), value2)
errcode = sd_protected_register_write(&(NRF_BPROT->CONFIG3), value3)
```

Required changes

Updated advertiser API

sd_ble_gap_adv_data_set() has been removed.

A new API, $sd_ble_gap_adv_set_configure()$, has been added with the following functionalities:

- Configuring and updating the advertising parameters of an advertising set.
- Setting, clearing, or updating advertising and scan response data.

Note: The advertising data must be kept alive in memory until advertising is terminated. Not doing so will lead to undefined behavior. Note: Updating advertising data while advertising can only be done by providing new advertising data buffers.

Configuring and updating an advertising set

Advertising Set is a term introduced in Bluetooth Core Specification v5.0.

Each advertising set is identified by an advertising handle. To configure a new advertising set and obtain a new advertising handle, sd_ble_gap_adv_set_configure() should be called with a pointer p_adv _handle pointing to an advertising handle set to BLE_GAP_ADV_SET_HANDLE_NOT_SET.

To update an existing advertising set, sd_ble_gap_adv_set_configure() should be called with a previously configured advertising handle.

Note: Currently only one advertising set can be configured in the SoftDevice.

Configuring advertising parameters for an advertising set

Setting advertising parameters has been moved from sd_ble_gap_adv_start() to sd_ble_gap_adv_set_configure().

The content of ble_gap_adv_params_t has changed:

- ble_gap_adv_params_t::type has been removed.
- A new parameter, properties, of the new type ble_gap_adv_properties_t has been added.
 - The advertising type must now be set through ble_gap_adv_properties_t::type.

- The advertising type definitions (BLE_GAP_ADV_TYPES) have changed, and new types have been added. The mapping from old to new advertising types is shown below. These advertising types are referred to as *legacy* advertising types:
 - type = BLE_GAP_ADV_TYPE_ADV_IND -> properties.type = BLE_GAP_ADV_TYPE_CONNECTABLE_SCANNABLE_UNDIRECTED
 - type = BLE_GAP_ADV_TYPE_ADV_DIRECT_IND -> properties.type = BLE_GAP_ADV_TYPE_CONNECTABLE_NONSCANNABLE_DIRECTED_HIGH_DUTY_CYCLE of BLE_GAP_ADV_TYPE CONNECTABLE NONSCANNABLE DIRECTED
 - type = BLE GAP ADV TYPE ADV SCAN IND -> properties.type = BLE GAP ADV TYPE NONCONNECTABLE SCANNABLE UNDIRECTED
 - type = BLE_GAP_ADV_TYPE_ADV_NONCONN_IND -> properties.type = BLE_GAP_ADV_TYPE_NONCONNECTABLE_NONSCANNABLE_UNDIRECTED
- ble_gap_adv_params_t::fp_has been renamed ble_gap_adv_params_t::filter_policy.
- ble_gap_adv_params_t::timeout has been renamed ble_gap_adv_params_t::duration and is now measured in 10 ms units.
- ble_gap_adv_params_t::channel_mask type has been changed from ble_gap_adv_ch_mask_t to the new type ble_gap_ch_mask_t.
 - Note: At least one of the primary channels that is channel index 37-39 must be set to 0.
 - Note: Masking away secondary channels is currently not supported.
 - The mapping from old type ble_gap_adv_ch_mask_t to the new type ble_gap_ch_mask_t is shown below:
 - channel_mask.ch_37_off = 1 -> channel_mask = 0x200000000
 - channel_mask.ch_38_off = 1 -> channel_mask = 0x400000000
 - channel_mask.ch_39_off = 1 -> channel_mask = 0x800000000
- ble_gap_adv_params_t has several new parameters:
 - max_adv_evts has been added to allow the application to advertise for a given number of advertising events.
 - scan_req_notification flag has been added to give the application the possibility to receive events of type ble_gap_evt_scan_req_report_t. This replaces BLE_GAP_OPT_SCAN_REQ_REPORT.
 - primary_phy and secondary_phy allow the application to select PHYs for primary and secondary advertising channels.
 - primary_phy should be set to BLE_GAP_PHY_AUTO or BLE_GAP_PHY_1MBPS for legacy advertising types. For extended advertising types, it should be set to BLE_GAP_PHY_1MBPS or BLE_GAP_PHY_CODED if supported by the SoftDevice.
 - secondary_phy can be ignored for legacy advertising. For extended advertising types, it should be set to BLE_GAP_PHY_1MBPS, BLE_GAP_PHY_2MBPS, or BLE_GAP_PHY_CODED if supported by the SoftDevice.
 - set_id has been added to allow the application to choose the set ID of an extended advertiser.

Other Advertising API changes

- BLE_GAP_TIMEOUT_SRC_ADVERTISING has been removed.
 - A new event, BLE_GAP_EVT_ADVERTISING_SET_TERMINATED with structure ble_gap_evt_adv_set_terminated_t, has been introduced to let the application know when and why an advertising set has terminated.
- A new configuration parameter, ble_gap_cfg_role_count_t::adv_set_count, has been introduced to set the maximum number of advertising sets. Note: The maximum number of supported adv ertising sets is BLE_GAP_ADV_SET_COUNT_MAX.
- **BLE_GAP_ADV_MAX_SIZE** has been replaced with **BLE_GAP_ADV_SET_DATA_SIZE_MAX**.
- ble_gap_evt_connected_t now includes adv_handle and adv_data of the new type ble_gap_adv_data_t. These are set when the device connects as a peripheral.
- ble_gap_evt_scan_req_report_t now includes adv_handle.
- BLE_GAP_OPT_SCAN_REQ_REPORT has been removed.
- BLE_GAP_ADV_TIMEOUT_LIMITED_MAX has been changed from 180 to 18000 as sd_ble_gap_adv_params_t::duration is now measured in 10 ms units.

```
static uint8 t raw adv data buffer1[BLE GAP ADV SET DATA SIZE MAX];
static uint8 t raw scan rsp data buffer1[BLE GAP ADV SET DATA SIZE MAX];
static ble gap adv data t adv data1 = {.adv data.p data = raw adv data buffer1,
                                                                                         .adv data.len
                                                                                                             =

/* Update advertising data while advertising */
sd_ble_gap_adv_set_configure(&adv_handle, &adv_data2, NULL);
[...]
/* Stop advertising */
sd_ble_gap_adv_stop(adv_handle);
[...]
}
```

Updated scanner API

The scanner API has been updated. The changes are as follows:

- ble_gap_scan_params_t has been changed:
 - A new flag, extended, has been added. If set to 1, the scanner will receive both legacy advertising packets and extended advertising packets. If set to 0, the extended advertising packets will be ignored.
 - The Observer channel map for primary advertising channels can be set through a new parameter ble_gap_scan_params_t::channel_mask. The parameter type ble_gap_ch_mask_t is the same as is used for setting advertiser channel map.
 - use_whitelist and adv_dir_report have been combined into filter_policy. See BLE_GAP_SCAN_FILTER_POLICIES for valid policies.
 - scan_phys has been added to let the application decide on which PHYs the scanner should receive packets. Set to BLE_GAP_PHY_AUTO or BLE_GAP_PHY_1MBPS if extended scanning is disabled.
 - timeout is now measured in 10 ms units.
- sd_ble_gap_scan_start() has a new input parameter, p_adv_report_buffer, which takes a pointer to an advertising report buffer that must be kept alive until the scanner is stopped. The minimum buffer size is either BLE_GAP_SCAN_BUFFER_MIN or BLE_GAP_SCAN_BUFFER_EXTENDED_MIN when extended scanning is enabled.
- When the application receives a ble_gap_adv_report_t, it must now resume scanning by calling sd_ble_gap_scan_start().
- ble_gap_evt_adv_report_t has been updated:
 - ble_gap_evt_adv_report_t::type has been redefined from uint8_t to ble_gap_adv_report_type_t.
 - scan_rsp flag has been removed. It is now included in ble_gap_adv_report_type_t::scan_response.
 - data and dlen have been replaced with data of type ble_data_t.
 - New fields have been added: and aux_pointer.
- ble_gap_evt_timeout_t now includes adv_report_buffer which is set when the scanner times out.
- BLE_GAP_SCAN_INTERVAL_MAX and BLE_GAP_SCAN_WINDOW_MAX have been increased from 0x4000 to 0xFFFF.

• BLE_GAP_SCAN_TIMEOUT_MAX has been removed.

```
static uint8 t raw scan buffer[BLE GAP SCAN BUFFER MIN];
static ble_data_t scan_buffer = {.p_data = raw_scan_buffer, .len = sizeof(raw_scan_buffer)};
void on_ble_evt(const ble_evt_t * p_evt)
  if (p ble evt->header.evt id == BLE GAP EVT ADV REPORT)
   ble_gap_evt_adv_report_t * p_report = &p_ble_evt->evt.gap_evt.params.adv_report;
   /* Read out data*/
    [...]
    /* Continue scanning. */
    sd ble gap scan start(NULL, &scan buffer);
  }
int main(void)
{
 ble gap scan params t scan params= {.extended
                                                  = 0,
                                                      .scan phys
                                                                     = BLE_GAP_PHY_AUTO,
                                      .timeout
                                                   = BLE_GAP_SCAN_TIMEOUT_UNLIMITED, /* Unlimited scanning */
                                      .interval
                                                    = BLE GAP SCAN INTERVAL MAX,
                                      .channel_mask = {0}, /* Scanning on all the primary channels */
                                      .filter_policy = BLE_GAP_SCAN_FP_ACCEPT_ALL
                                     };
  /* Enable the BLE Stack */
```

```
sd_ble_enable(...);
/* Start scanning */
sd_ble_gap_scan_start(&scan_params, &scan_buffer);
[...]
}
```

Updated RSSI API

The RSSI API has been changed so that the SoftDevice can provide the application with the channel index on which the reported RSSI measurements are made.

- sd_ble_gap_rssi_get() takes an additional parameter p_ch_index. For this parameter, provide a pointer to a location where the channel index for the RSSI measurement should be stored.
- The event structure for the BLE_GAP_EVT_RSSI_CHANGED event has a new parameter ble_gap_evt_rssi_changed_t::ch_index. This is the Data Channel Index (0-36) on which the RSSI is measured.
- The event structure for the BLE_GAP_EVT_ADV_REPORT event has a new parameter ble_gap_evt_adv_report_t::ch_index. This is the Channel Index (0-39) on which the last advertising packet is received. The corresponding measured RSSI for this packet can be read from ble_gap_evt_adv_report_t::rssi.

TX power API

The TX power API now supports setting individual transmit power for each link or role.

• sd_ble_gap_tx_power_set() takes two new parameters, role and handle, in addition to tx_power. For available roles and TX power values, see ble_gap.h.

Updated Flash API

sd_flash_write() now triggers a HardFault if the application tries to write to a protected page. NRF_ERROR_FORBIDDEN is returned if the application tries to write to a page outside application flash area.

sd_flash_page_erase() now triggers a HardFault if the application tries to erase a protected page. NRF_ERROR_FORBIDDEN is returned if the application tries to erase a page outside application flash area.

s132_nrf52_5.0.0

This section describes how to migrate to s132_nrf52_5.0.0 from s132_nrf52_4.0.3.

Required changes

SoftDevice flash and RAM usage

The size of the SoftDevice has changed requiring a change to the application project file.

For Keil this means:

- Go into the properties of the project and find the Target tab
- Change IROM1 Start to 0x23000.

If the project uses a scatter file or linker script instead, they must be updated accordingly.

The RAM usage of the SoftDevice has also changed. sd_ble_enable() should be used to find the APP_RAM_BASE for a particular configuration.

API renaming and updates

Some APIs are renamed or removed. Applications that use the old API names must be updated:

- The timeout source BLE_GAP_TIMEOUT_SRC_SECURITY_REQUEST has been removed. Use the existing BLE_GAP_EVT_AUTH_STATUS {auth_status: BLE_GAP_SEC_STATUS_TIMEOUT} instea
 d.
- BLE_GAP_ADV_NONCON_INTERVAL_MIN has been removed because the lower limit for the advertising interval for non-connectable advertisement has been lowered to BLE_GAP_ADV_INTERVAL_MIN.
- The compatibility mode BLE_GAP_OPT_COMPAT_MODE_2 is removed because the SoftDevice now accepts overlapping peer-initiated Link Layer control procedures as a slave.
- NRF_ERROR_BUSY will no longer be returned by sd_ble_gap_adv_start(), sd_ble_gap_scan_start(), sd_ble_gap_authenticate() and sd_ble_gap_connect().
- NRF_ERROR_BUSY can now be returned when calling sd_ble_user_mem_reply(), sd_ble_gatts_rw_authorize_reply() or sd_ble_gap_sec_params_reply().
- NRF_CLOCK_LF_XTAL_ACCURACY renamed to NRF_CLOCK_LF_ACCURACY
- nrf_clock_lf_cfg_t struct member xtal_accuracy renamed to accuracy.
- A new event BLE_GAP_EVT_PHY_UPDATE_REQUEST has been added. The application must check for this event and respond to it by calling the SV call sd_ble_gap_phy_update(). For more information, please refer to the 2 Mbps PHY support section in New functionality.

RC Oscillator accuracy

The RC oscillator accuracy can now be set to any of the defined NRF_CLOCK_LF_ACCURACY values and there is no default value anymore. In other words, the nrf_clock_lf_cfg_t::accuracy parameter now has the same functionality when used with the RCOSC clock source as with the XTAL clock source. The RC oscillator accuracy should be set to a value appropriate for the chip.

New functionality

2 Mbps PHY support

This SoftDevice supports 2 Mbps PHY data transmission for already established connections. Either the application or the peer can request switching to 2 Mbps PHY in order to achieve higher throughput. Both sides need to agree on the PHYs before a PHY change can occur. The application has to respond to the PHY Update procedure when that is initiated by the peer, otherwise the link will be disconnected. This makes it necessary for the application to pull a new event: BLE_GAP_EVT_PHY_UPDATE_REQUEST. Another event, BLE_GAP_EVT_PHY_UPDATE, may be raised when a PHY Update procedure is completed but the application is not required to take any actions for this event.

API Updates

• A new SV call, sd_ble_gap_phy_update(), has been added to request the controller to attempt to change to a new PHY, or to respond to a peer-initiated PHY Update procedure.

Usage

```
ble_gap_phys_t phys = {BLE_GAP_PHY_2MBPS, BLE_GAP_PHY_2MBPS};
sd ble gap phy update(conn handle, &phys);
```

• A new event, BLE_GAP_EVT_PHY_UPDATE_REQUEST, has been added to notify the application that the peer has initiated a PHY Update procedure, to which the application must respond with its PHY preferences.

• A new event, BLE_GAP_EVT_PHY_UPDATE, has been added to notify the application that a self-initiated or peer-initiated PHY Update procedure has been completed.

```
case BLE_GAP_EVT_PHY_UPDATE_REQUEST:
{
   /* The PHYs requested by the peer can be read from the event parameters: p_ble_evt->evt.gap_evt.params.
   phy_update_request.peer_preferred_phys.
    * Note that the peer's TX correponds to our RX and vice versa. */
```

```
/* Allow SoftDevice to choose PHY Update Procedure parameters automatically. */
ble_gap_phys_t phys = {BLE_GAP_PHY_AUTO, BLE_GAP_PHY_AUTO};
sd_ble_gap_phy_update(p_ble_evt->evt.gap_evt.conn_handle, &phys);
break;
}
case BLE_GAP_EVT_PHY_UPDATE:
{
    if (p_ble_evt->evt.gap_evt.params.phy_update.status == BLE_HCI_STATUS_CODE_SUCCESS)
    {
        /* PHY Update Procedure completed, see p_ble_evt->evt.gap_evt.params.phy_update.tx_phy and p_ble_evt->evt.
gap_evt.params.phy_update.rx_phy for the currently active PHYs of the link. */
    }
    break;
}
```

Connection-Oriented Channels in LE Credit Based Flow Control Mode

The SoftDevice now supports Connection-Oriented Channels in the LE Credit Based Flow Control Mode. To be able to use this feature, the application has to set an L2CAP connection configuration using the configuration API sd_ble_cfg_set() as shown below.

```
      Setting L2CAP Connection Configuration

      /* Set L2CAP Connection Configuration for connection identified by coc_conn_cfg_tag */
ble_cfg_t cfg;
memset(&cfg, 0, sizeof(ble_cfg_t));
cfg.conn_cfg.conn_cfg_tag = coc_conn_cfg_tag;
cfg.conn_cfg.params.l2cap_conn_cfg.rx_mps = BLE_L2CAP_MPS_MIN;
```

```
cfg.conn_cfg.params.l2cap_conn_cfg.tx_mps = BLE_L2CAP_MPS_MIN;
cfg.conn_cfg.params.l2cap_conn_cfg.rx_queu_size = 5;
cfg.conn_cfg.params.l2cap_conn_cfg.ch_count = 1;
sd_ble_cfg_set(BLE_CONN_CFG_L2CAP, &cfg, ...);
[...]
/* Enable the BLE Stack */
sd_ble_enable(...);
```

The usage of some of the SV calls and events related to this feature is explained below. For the complete list of SV calls and events, please refer to the API documentation available in ble_l2cap.h.

A new SV call, sd_ble_l2cap_ch_setup(), has been added to request the setup of an L2CAP channel, or to respond to a setup request from a peer.

Creating a new L2CAP Channel		
uint16_t	local_cid = BLE_L2CAP_CID_INVALID;	
<pre>ble_l2cap_ch_setup_params_t ch_setup_params;</pre>		
ch_setup_params.le_psm	= 0x25;	
ch_setup_params.rx_params.rx_mtu	= BLE_L2CAP_MTU_MIN;	
ch_setup_params.rx_params.rx_mps	= BLE_L2CAP_MPS_MIN;	
ch_setup_params.rx_params.sdu_buf	= NULL;	
<pre>sd_ble_l2cap_ch_setup(conn_handle, &</pre>	<pre>local_cid, &ch_setup_params);</pre>	

Res	ponding to a L2CAP Channel setup request			
case BLE_L2CAP_EVT_CH_SETUP_REQUEST:				
{ /* An L2CAP channel setup request has be	/* An L2CAP channel setup request has been received from the peer. */			
uint16_t	<pre>local_cid = p_ble_evt->evt.l2cap_evt.local_cid;</pre>			
ble_l2cap_ch_setup_params_t ch_setup_par	rams;			
<pre>ch_setup_params.le_psm ch_setup_params.rx_params.rx_mtu ch_setup_params.rx_params.rx_mps ch_setup_params.rx_params.sdu_buf = NULI sd_ble_l2cap_ch_setup(p_ble_evt->evt.l2c</pre>				
break; }				

The SV call sd_ble_l2cap_ch_tx() can be used to transmit an SDU (Service Data Unit) on an L2CAP channel. The event BLE_L2CAP_EVT_CH_TX is generated by the SoftDevice to notify the application that the SDU has been transmitted.

Transmitting on an L2CAP Channel	
ble_data_t sdu_to_send; uint8_t data[] = "Sample";	
<pre>sdu_to_send.len = strlen(data); sdu_to_send.p_data = data;</pre>	

```
sd_ble_l2cap_ch_tx(conn_handle, local_cid, &sdu_to_send);
[...]
case BLE_L2CAP_EVT_CH_TX:
   /* The SDU is transmitted. */
   break;
[...]
```

The SV call sd_ble_l2cap_ch_rx() shall be used to provide the SoftDevice with a buffer to receive an SDU from the peer. The event BLE_L2CAP_EVT_CH_RX is generated by the SoftDevice to notify the application that an SDU has been received. The application shall not change the buffer provided to the SoftDevice before receiving the event.

```
Receiving on an L2CAP Channel
[...]
ble_data_t sdu_buf;
uint8_t data[150];
sdu_buf.len = strlen(data);
sdu_buf.p_data = data;
sd_ble_l2cap_ch_rx(conn_handle, local_cid, &sdu_buf));
[...]
case BLE_L2CAP_EVT_CH_RX:
    /* An SDU is received by the SoftDevice from the peer and is available in p_ble_evt->evt.l2cap_evt.params.rx.
```

sdu_buf */	
break;	
[]	

Network Privacy Mode

The SoftDevice now supports the Network Privacy Mode. In Network Privacy Mode, a device will only accept advertising packets from peer devices that contain private addresses.

API Updates

- A new mode, BLE_GAP_PRIVACY_MODE_NETWORK_PRIVACY, is added to enable Network Privacy Mode.
- A new characteristic, BLE_UUID_GAP_CHARACTERISTIC_RPA_ONLY (RPA = Resolvable Private Address), is defined to let the application add this characteristic to the attribute database.

Usage

Set the privacy settings to network privacy with random private resolvable address:

ble_gap_privacy_params_t privacy_params = {0}; privacy_params.privacy_mode = BLE_GAP_PRIVACY_MODE_NETWORK_PRIVACY; privacy_params.private_addr_type = BLE_GAP_ADDR_TYPE_RANDOM_PRIVATE_RESOLVABLE; sd_ble_gap_privacy_set(privacy_params);

Unique string to identify a SoftDevice

The SoftDevice Information Structure now also contains a string, namely the SoftDevice unique string, that can be used to uniquely identify a version of the SoftDevice (applies also for alpha releases).

Usage

```
Fetching the SoftDevice unique string
/* Declare a character array that is twice the length of the SoftDevice unique string.
* This will be used to store the hexadecimal representation of the SoftDevice unique string. */
char str[SD_UNIQUE_STR_SIZE * 2];
/* Fetch the address of the SoftDevice unique string. */
const uint8_t * const p_unique_str = SD_UNIQUE_STR_ADDR_GET(MER_SIZE);
/* Read the SoftDevice unique string into the character array, converting it into hexadecimal notation. */
for (uint8_t i = 0; i < SD_UNIQUE_STR_SIZE; i++)
{
    sprintf(&str[i * 2], "%02x", p_unique_str[i]);
    /* The SoftDevice unique string is now available in the character array named str. */</pre>
```

Other API additions and changes

- The status code BLE_HCI_STATUS_CODE_LMP_ERROR_TRANSACTION_COLLISION indicates that there has been an illegal collision of LL Control PDUs on air.
- A new MBR command SD_MBR_COMMAND_IRQ_FORWARD_ADDRESS_SET has been added to forward all interrupts to another base address.
- New defines for minimum and maximum values of authenticated payload timeout have been added. See BLE_GAP_AUTH_PAYLOAD_TIMEOUT.
- A flag lesc is added to the ble_gap_evt_auth_status_t struct, indicating whether an authentication procedure resulted in an LE Secure Connection.
- The SoftDevice will no longer return NRF_ERROR_BUSY on sd_ble_gap_conn_param_update() unless the procedure is already in progress.
- The new definitions NRF_RADIO_MAX_EXTENSION_PROCESSING_TIME_US and NRF_RADIO_MIN_EXTENSION_MARGIN_US define timing constraints the application must take into account when using NRF_RADIO_SIGNAL_CALLBACK_ACTION_EXTEND with the Radio Timeslot API.

s132_nrf52_4.0.3

This section describes how to migrate to s132_nrf52_4.0.3 from s132_nrf52_3.0.0.

Required changes

SoftDevice RAM usage

The RAM usage of the SoftDevice has changed. sd_ble_enable() should be used to find the APP_RAM_BASE for a particular configuration.

New configuration API

Configuration parameters passed to sd_ble_enable() have been moved to the SoftDevice configuration API.

API updates

- A new SV call sd_ble_cfg_set() is added to set the configuration. This API can be called many times to configure different parts of the BLE stack. All configurations are optional. Configuration parameters not set by this API will take their default values.
- The SV call parameter ble_enable_params_t * p_ble_enable_params is removed from sd_ble_enable(). The SV call sd_ble_cfg_set() must be used instead. The parameters of this call are given in the following table:

Old API: ble_enable_params_t member	New API: cfg_id in sd_ble_cfg_set()
common_enable_params.vs_uuid_count	BLE_COMMON_CFG_VS_UUID
common_enable_params.p_conn_bw_counts	BLE_CONN_CFG_GAP (*)
<pre>gap_enable_params.periph_conn_count gap_enable_params.central_conn_count gap_enable_params.central_sec_count</pre>	BLE_GAP_CFG_ROLE_COUNT
gap_enable_params.p_device_name	BLE_GAP_CFG_DEVICE_NAME
gatt_enable_params	BLE_CONN_CFG_GATT (*)
gatts_enable_params.service_changed	BLE_GATTS_CFG_SERVICE_CHANGED
gatts_enable_params.attr_tab_size	BLE_GATTS_CFG_ATTR_TAB_SIZE

(*) These configurations can be set per link.

Usage

Example pseudo code to set per link ATT_MTU using the new configuration API:

```
const uint16 t client rx mtu = 158;
const uint32_t long_att_conn_cfg_tag = 1;
/* set ATT_MTU for connections identified by long_att_conn_cfg_tag */
ble cfq t cfq;
memset(&cfg, 0, sizeof(ble_cfg_t));
cfg.conn_cfg_tag = long_att_conn_cfg_tag;
cfg.conn_cfg.params.gatt_conn_cfg.att_mtu = client_rx_mtu;
sd_ble_cfg_set(BLE_CONN_CFG_GATT, &cfg, ...);
/* Enable the BLE Stack */
sd ble enable(...);
[...]
uint16_t long_att_conn_handle;
/* Establish connection with long att conn cfg tag */
sd_ble_gap_adv_start(..., long_att_conn_cfg_tag);
[...]
/* Establish connection with BLE CONN CFG TAG DEFAULT, it will use default ATT MTU of 23 bytes */
sd_ble_gap_connect(..., BLE_CONN_CFG_TAG_DEFAULT);
```

[...]

```
/* Start ATT_MTU exchange */
sd_ble_gattc_exchange_mtu_request(long_att_conn_handle, client_rx_mtu);
```

BLE bandwidth configuration

The BLE bandwidth configuration and application packet concept has been changed. Previously, the application could specify a bandwidth setting, which would result in a given queue size and a correpsonding given radio time allocated. Now the queue sizes and the allocated radio time have been separated. The application can now configure:

- Event length
- Write without response queue size
- Handle Value Notification queue size

These settings are configurable per link.

Note that now the configured queue sizes are not directly related to on-air bandwidth:

- The application can configure one single packet to be queued in the SoftDevice, but still achieve full throughput if the application can queue packets fast enough during connection events.
- Even if the application configures a large number of packets to be queued, not all of them will be sent during a single connection event if the configured event length is not large enough to send the packets.

API updates

• The ble_enable_params_t::common_enable_params.p_conn_bw_counts parameter of the sd_ble_enable() SV call is replaced by the sd_ble_cfg_set() SV call with cfg_id parameter set to BLE_CONN_CFG_GAP. The following table shows how the old bandwidth configuration corresponds to the new one for the default ATT_MTU:

Old API: BLE_CONN_BWS	New API: ble_gap_conn_cfg_t::event_length in sd_ble_cfg_set()	
BLE_CONN_BW_LOW	BLE_GAP_EVENT_LENGTH_MIN	
BLE_CONN_BW_MID	BLE_GAP_EVENT_LENGTH_DEFAULT	
BLE_CONN_BW_HIGH	6	

The bandwidth configuration is further described in the SDS.

- The BLE_COMMON_OPT_CONN_BW option is removed. Instead, during connection creation, the application should supply the conn_cfg_tag defined by the ble_conn_cfg_t::conn_cfg_tag
 parameter in the sd_ble_cfg_set()
 SV call.
- A new parameter conn_cfg_tag is added to sd_ble_gap_adv_start() and sd_ble_gap_connect() SV calls. To create a connection with a default configuration, BLE_CONN_CFG_TAG_DEFAULT should be provided in this parameter.
- The **BLE_EVT_TX_COMPLETE** event is split on two events: **BLE_GATTC_EVT_WRITE_CMD_TX_COMPLETE** and **BLE_GATTS_EVT_HVN_TX_COMPLETE**.

• The SV call sd_ble_tx_packet_count_get() is removed. Instead, the application can now configure packet counts per link, using the SV call sd_ble_cfg_set() with the cfg_id parameter set to BLE_CONN_CFG_GATTC and BLE_CONN_CFG_GATTS.

Usage

Example pseudo code to set configuration that corresponds to the old BLE_CONN_BW_HIGH bandwidth configuration both in throughput and packet queueing capability:

```
const uint32 t high by conn cfg tag = 1;
ble cfq t cfq;
/* configure connections identified by high bw conn cfg tag */
/* set connection event length */
memset(&cfq, 0, sizeof(ble cfq t));
cfg.conn_cfg.conn_cfg_tag = high_bw_conn_cfg_tag;
cfq.conn cfq.params.qap conn cfq.event length = 6; /* 6 * 1.25 ms = 7.5 ms corresponds to the old
BLE CONN BW HIGH for default ATT MTU */
cfg.conn_cfg.params.gap_conn_cfg.conn_count = 1; /* application needs one link with this configuration */
sd ble cfq set(BLE CONN CFG GAP, &cfq, ...);
/* set HVN queue size */
memset(&cfq, 0, sizeof(ble cfq t));
cfg.conn_cfg.conn_cfg_tag = high_bw_conn_cfg_tag;
cfq.conn cfq.params.gatts conn cfq.hvn tx queue size = 7; /* application wants to queue 7 HVNs */
sd ble cfq set(BLE CONN CFG GATTS, &cfq, ...);
/* set WRITE CMD queue size */
memset(&cfq, 0, sizeof(ble cfq t));
cfg.conn_cfg.conn_cfg_tag = high_bw_conn_cfg_tag;
cfq.conn cfq.params.gattc conn cfq.write cmd tx queue size = 0; /* application is not going to send WRITE CMD,
so set to 0 to save memory */
sd_ble_cfg_set(BLE_CONN_CFG_GATTC, &cfg, ...);
```

```
/* Enable the BLE Stack */
sd_ble_enable(...);
[...]
uint16_t high_bw_conn_handle;
/* Establish connection with high_bw_conn_cfg_tag */
sd_ble_gap_adv_start(..., high_bw_conn_cfg_tag);
```

Data Length Update Procedure

The application now has to respond to the Data Length Update Procedure when initiated by the peer. See the description of the Data Length Update Procedure in the New functionality section for more details. Required changes:

```
case BLE_GAP_EVT_DATA_LENGTH_UPDATE_REQUEST:
{
    /* Allow SoftDevice to choose Data Length Update Procedure parameters automatically. */
    sd_ble_gap_data_length_update(p_ble_evt->evt.gap_evt.conn_handle, NULL, NULL);
    break;
}
case BLE_GAP_EVT_DATA_LENGTH_UPDATE:
{
    /* Data Length Update Procedure completed, see p_ble_evt->evt.gap_evt.params.data_length_update.
effective_params for negotiated parameters. */
    break;
}
```

Access to RAM[x]. POWER registers

SoftDevice APIs are updated to provide access to the RAM[x]. POWER registers instead of the deprecated RAMON/RAMONB.

API updates

- sd_power_ramon_set() SV call is replaced with sd_power_ram_power_set().
- sd_power_ramon_clr() SV call is replaced with sd_power_ram_power_clr().
- sd_power_ramon_get() SV call is replaced with sd_power_ram_power_get().

API rename

Some APIs were renamed. Applications that use the old names must be updated.

API updates

- **BLE_EVTS_PTR_ALIGNMENT** is renamed to **BLE_EVT_PTR_ALIGNMENT**.
- **BLE_EVTS_LEN_MAX** is renamed to **BLE_EVT_LEN_MAX**.
- GATT_MTU_SIZE_DEFAULT is renamed to BLE_GATT_ATT_MTU_DEFAULT.
- The GAP option <u>BLE_GAP_OPT_COMPAT_MODE</u> is renamed to <u>BLE_GAP_OPT_COMPAT_MODE_1</u>.
- ble_gap_opt_compat_mode_t structure is renamed to ble_gap_opt_compat_mode_1_t.
- ble_gap_opt_compat_mode_t::mode_1_enable structure member is renamed to ble_gap_opt_compat_mode_1_t::enable.
- ble_gap_opt_t::compat_mode structure member is renamed to ble_gap_opt_t::compat_mode_1.

Proprietary L2CAP API removed

The proprietary API for sending and receiving data over L2CAP is removed.

API updates

- The SV calls sd_ble_l2cap_cid_register(), sd_ble_l2cap_cid_unregister(), and sd_ble_l2cap_tx() are removed.
- BLE_L2CAP_EVT_RX event is removed.
- The following defines are removed: BLE_L2CAP_MTU_DEF, BLE_L2CAP_CID_INVALID, BLE_L2CAP_CID_DYN_BASE, BLE_L2CAP_CID_DYN_MAX.

New functionality

Data Length Update Procedure

The application is given control of the Data Length Update Procedure. The application can initiate the procedure and has to respond when initiated by the peer.

API updates

- A new SV call sd_ble_gap_data_length_update() is added to initiate or respond to a Data Length Update Procedure.
- The **BLE_EVT_DATA_LENGTH_CHANGED** event is replaced with **BLE_GAP_EVT_DATA_LENGTH_UPDATE**.

```
• A new event BLE_GAP_EVT_DATA_LENGTH_UPDATE_REQUEST is added to notify that a Data Length Update request has been received. sd_ble_gap_data_length_update() must be called by the application after this event has been received to continue the Data Length Update Procedure.
```

• The GAP option <u>BLE_GAP_OPT_EXT_LEN</u> is removed. The sd_ble_gap_data_length_update() SV call should be used instead.

Usage

- The Data Length Update Procedure can be initiated locally or by peer device.
- Following is the pseudo code for the case where Data Length Update Procedure is initiated by application:

```
const uint16 t client rx mtu = 247;
const uint32_t long_att_conn_cfg_tag = 1;
/* ATT MTU must be configured first */
ble cfq t cfq;
memset(&cfq, 0, sizeof(ble cfq t));
cfq.conn cfq.conn cfq taq = long att conn cfq taq;
cfg.conn_cfg.params.gatt_conn_cfg.att_mtu = client_rx_mtu;
sd ble cfg set(BLE CONN CFG GATT, &cfg, ...);
/* Enable the BLE Stack */
sd ble enable(...);
[...]
uint16_t long_att_conn_handle;
/* Establish connection */
sd ble gap adv start(..., long att conn cfg tag);
[...]
/* Start Data Length Update Procedure, can be done without ATT MTU exchange */
```

```
ble_gap_data_length_params_t params = {
    .max_tx_octets = client_rx_mtu + 4,
    .max_rx_octets = client_rx_mtu + 4,
    .max_tx_time_us = BLE_GAP_DATA_LENGTH_AUTO,
    .max_rx_time_us = BLE_GAP_DATA_LENGTH_AUTO
};
sd_ble_gap_data_length_update(long_att_conn_handle, &params, NULL);
[...]
case BLE_GAP_EVT_DATA_LENGTH_UPDATE:
{
    /* Data Length Update Procedure completed, see p_ble_evt->evt.gap_evt.params.data_length_update.
effective_params for negotiated parameters. */
    break;
}
```

New compatibility mode

A new compatibility mode is added to enable interoperability with central devices that may initiate version exchange and feature exchange control procedures in parallel. To enable this mode, use the sd_ble_op t_set() SV call with the opt_id parameter set to BLE_GAP_OPT_COMPAT_MODE_2.

Slave latency configuration

It is now possible to disable and enable slave latency on an active peripheral link. To disable or re-enable slave latency, use the sd_ble_opt_set() SV call with the opt_id parameter set to BLE_GAP_OPT_S LAVE_LATENCY_DISABLE.

Support for high accuracy LFCLK oscillator source

It is now possible to configure the SoftDevice with higher accuracy LFCLK oscillator source. Four new levels are defined:

#define N	IRF_CLOCK_LF_	XTAL_ACCURACY_	_10_PPM (8) /**<	10	ppm	*/
#define N	IRF_CLOCK_LF_	XTAL_ACCURACY_	_5_PPM (9) /**<	5	ppm	*/
#define N	NRF_CLOCK_LF_	XTAL_ACCURACY_	_2_PPM (10) /**<	2	ppm	*/
#define N	JRF_CLOCK_LF_	XTAL_ACCURACY_	_1_PPM (11) /**<	1	ppm	*/

RC oscillator: "xtal_accuracy" must be configured

In previous versions of the SoftDevice, the xtal_accuracy was ignored by the API when RCOSC was selected as the low frequency clock source. The default configuration used was 250 ppm. The RC oscillator accuracy must now be configured by setting nrf_clock_lf_cfg_t::xtal_accuracy to NRF_CLOCK_LF_XTAL_ACCURACY_250_PPM to maintain the behavior of previous SoftDevices. The only other valid configuration is NRF_CLOCK_LF_XTAL_ACCURACY_500_PPM. If the xtal_accuracy is set to any value other than 250 ppm or 500 ppm, a default configuration of 500 ppm will be applied.

New power failure levels

It is now possible to configure the SoftDevice with all the new power failure levels introduced in NRF52. Levels that are added:

NRF_POWER_THRESHOLD_V17/**< Set the power failure threshold to 1.7 V. */NRF_POWER_THRESHOLD_V18/**< Set the power failure threshold to 1.8 V. */NRF_POWER_THRESHOLD_V19/**< Set the power failure threshold to 1.9 V. */NRF_POWER_THRESHOLD_V20/**< Set the power failure threshold to 2.0 V. */NRF_POWER_THRESHOLD_V22/**< Set the power failure threshold to 2.2 V. */NRF_POWER_THRESHOLD_V24/**< Set the power failure threshold to 2.4 V. */NRF_POWER_THRESHOLD_V26/**< Set the power failure threshold to 2.6 V. */NRF_POWER_THRESHOLD_V28/**< Set the power failure threshold to 2.8 V. */	NRF_POWER_THRESHOLD_V18/**< Set the power failure threshold to 1.8 V. */	//////////////////////////////////////	
NRF_POWER_THRESHOLD_V18/**< Set the power failure threshold to 1.8 V. */NRF_POWER_THRESHOLD_V19/**< Set the power failure threshold to 1.9 V. */	NRF_POWER_THRESHOLD_V18/**< Set the power failure threshold to 1.8 V. */NRF_POWER_THRESHOLD_V19/**< Set the power failure threshold to 1.9 V. */	NRE POWER THRESHOLD V17	/**< Set the power failure threshold to 1.7 V */
NRF_POWER_THRESHOLD_V19/**< Set the power failure threshold to 1.9 V. */NRF_POWER_THRESHOLD_V20/**< Set the power failure threshold to 2.0 V. */	NRF_POWER_THRESHOLD_V19/**< Set the power failure threshold to 1.9 V. */NRF_POWER_THRESHOLD_V20/**< Set the power failure threshold to 2.0 V. */	MRF_FOWER_FIREDHOLD_VFV	
NRF_POWER_THRESHOLD_V20/**< Set the power failure threshold to 2.0 V. */NRF_POWER_THRESHOLD_V22/**< Set the power failure threshold to 2.2 V. */	NRF_POWER_THRESHOLD_V20/**< Set the power failure threshold to 2.0 V. */NRF_POWER_THRESHOLD_V22/**< Set the power failure threshold to 2.2 V. */	NRF_POWER_THRESHOLD_V18	/**< Set the power failure threshold to 1.8 V. */
NRF_POWER_THRESHOLD_V22/**< Set the power failure threshold to 2.2 V. */NRF_POWER_THRESHOLD_V24/**< Set the power failure threshold to 2.4 V. */	NRF_POWER_THRESHOLD_V22/**< Set the power failure threshold to 2.2 V. */NRF_POWER_THRESHOLD_V24/**< Set the power failure threshold to 2.4 V. */	NRF_POWER_THRESHOLD_V19	/**< Set the power failure threshold to 1.9 V. */
NRF_POWER_THRESHOLD_V22/**< Set the power failure threshold to 2.2 V. */NRF_POWER_THRESHOLD_V24/**< Set the power failure threshold to 2.4 V. */	NRF_POWER_THRESHOLD_V22/**< Set the power failure threshold to 2.2 V. */NRF_POWER_THRESHOLD_V24/**< Set the power failure threshold to 2.4 V. */	NRF_POWER_THRESHOLD_V20	/**< Set the power failure threshold to 2.0 V. $*/$
NRF_POWER_THRESHOLD_V24/**< Set the power failure threshold to 2.4 V. */NRF_POWER_THRESHOLD_V26/**< Set the power failure threshold to 2.6 V. */	NRF_POWER_THRESHOLD_V24/**< Set the power failure threshold to 2.4 V. */NRF_POWER_THRESHOLD_V26/**< Set the power failure threshold to 2.6 V. */		
NRF_POWER_THRESHOLD_V26 /**< Set the power failure threshold to 2.6 V. */	NRF_POWER_THRESHOLD_V26 /**< Set the power failure threshold to 2.6 V. */	NRF_POWER_IHRESHOLD_V22	/ ^ < Set the power latture threshold to 2.2 V. /
		NRF_POWER_THRESHOLD_V24	/**< Set the power failure threshold to 2.4 V. */
NRF_POWER_THRESHOLD_V28 /**< Set the power failure threshold to 2.8 V. */	NRF_POWER_THRESHOLD_V28 /**< Set the power failure threshold to 2.8 V. */	NRF_POWER_THRESHOLD_V26	/**< Set the power failure threshold to 2.6 V. */
		NRF_POWER_THRESHOLD_V28	/**< Set the power failure threshold to 2.8 V. */

s132_nrf52_3.0.0

This section describes how to migrate to s132_nrf52_3.0.0 from s132_nrf52_2.0.1.

Required changes

SoftDevice flash and RAM usage

The size of the SoftDevice has changed requiring a change to the application project file.

For Keil this means:

- Go into the properties of the project and find the Target tab
- Change IROM1 Start to 0x1F000.

If the project uses a scatter file or linker script instead, those must be updated accordingly.

The RAM usage of SoftDevice has also changed. sd_ble_enable() should be used to find the APP_RAM_BASE for a particular configuration.

LL Privacy

This SoftDevice brings in support for LL Privacy. All applications must be updated to the new Privacy API and whitelist API supporting this new feature. Refer to the description of LL privacy in the New functionality section for more details.

Required changes:

Enable privacy

```
/* S132 v2.0 API usage */
ble_gap_addr_t private_addr = {0};
private_addr.addr_type = BLE_GAP_ADDR_TYPE_RANDOM_PRIVATE_RESOLVABLE;
sd_ble_gap_addr_set(BLE_GAP_ADDR_CYCLE_MODE_AUTO, private_addr);
```

```
/* S132 v3.0 API usage */
```

ble_gap_privacy_params_t privacy_params = {0}; privacy_params.privacy_mode = BLE_GAP_PRIVACY_MODE_DEVICE_PRIVACY; privacy_params.private_addr_type = BLE_GAP_ADDR_TYPE_RANDOM_PRIVATE_RESOLVABLE; sd_ble_gap_privacy_set(privacy_params);

Disable privacy

/* S132 v2.0 API usage */

```
ble_gap_addr_t identity_addr = saved_identity_addr; /* From sd_ble_gap_addr_get(). */
sd_ble_gap_addr_set(BLE_GAP_ADDR_CYCLE_MODE_NONE, identity_addr);
```

```
/* S132 v3.0 API usage */
```

ble_gap_privacy_params_t privacy_params = {0};
privacy_params.privacy_mode = BLE_GAP_PRIVACY_MODE_OFF;
sd_ble_gap_privacy_set(privacy_params);

• Whitelist private addresses

```
/* S132 v2.0 API usage */
/* Public devices. */
ble_gap_addr_t public_device1 = {
   .addr_type = BLE_GAP_ADDR_TYPE_PUBLIC,
```

```
.addr = {0x01, 0x02, 0x03, 0x04, 0x05, 0x06}};
ble_gap_addr_t public_device2 = {
   .addr_type = BLE_GAP_ADDR_TYPE_PUBLIC,
   .addr = {0x10, 0x20, 0x30, 0x40, 0x50, 0x60}};
/* IRKs of Private devices. */
ble_gap_irk_t irk1 = { .irk = { 0x10, 0x20, 0x30 /*...*/} };
ble_gap_irk_tt irk2 = { .irk = { 0x01, 0x02, 0x03 /*...*/} };
ble_gap_addr_t * whitelist_addrs[2] = {&public_device1, &public_device2};
ble_gap_whitelist_t whitelist = {
   .pp_addrs = &whitelist_addrs, .addr_count = 2, /* Public devices. */
   .pp_irks = &whitelist_irks, .irk_count = 2, /* Private devices. */};
ble_gap_adv_params_t adv_params = {0};
adv_params.p_whitelist = &whitelist = &whitelist
```

```
sd_ble_gap_adv_start(&adv_params);
```

/* S132 v3.0 API usage */

```
ble_gap_addr_t public_device1 = {
   .addr_type = BLE_GAP_ADDR_TYPE_PUBLIC,
   .addr = {0x01, 0x02, 0x03, 0x04, 0x05, 0x06},
};
ble_gap_addr_t public_device2 = {
   .addr_type = BLE_GAP_ADDR_TYPE_PUBLIC,
   .addr = {0x10, 0x20, 0x30, 0x40, 0x50, 0x60},
};
   /* Private devices. Matches addresses in identity list. */
ble_gap_addr_t private_device1 = {
```

```
.addr_type = BLE_GAP_ADDR_TYPE_PUBLIC,
  .addr = \{0xA1, 0xA2, 0xA3, 0xA4, 0xA5, 0xA6\}
};
ble_gap_addr_t private_device2 = {
  .addr_type = BLE_GAP_ADDR_TYPE_PUBLIC,
  .addr = \{0x1A, 0x2A, 0x3A, 0x4A, 0x5A, 0x6A\},\
};
ble gap addr t * whitelist[4] = {
  &public_device1, &public_device2,
  &private_device1, &private_device2,
};
ble_gap_id_key_t identity1 = {
  .id_addr_info = {
    .addr type = BLE GAP ADDR TYPE PUBLIC,
    .addr = \{0xA1, 0xA2, 0xA3, 0xA4, 0xA5, 0xA6\}, \}
  .id info ={
      .irk = { 0x10, 0x20, 0x30 /*...*/},
};
ble gap id key t identity2 = {
  .id addr info = {
    .addr_type = BLE_GAP_ADDR_TYPE_PUBLIC,
    .addr = \{0x1A, 0x2A, 0x3A, 0x4A, 0x5A, 0x6A\}, \}
  .id info = {
        .irk = { 0x01, 0x02, 0x03 /*...*/},
};
ble gap id key t * identities[2] = { &identity1, &identity2 };
sd ble qap device identities set(&identities, NULL /* Don't use local IRKs*/, 2);
sd_ble_gap_whitelist_set(&whitelist, 4);
ble gap adv params t adv params = {0};
adv_params.fp = BLE_GAP_ADV_FP_FILTER_BOTH;
sd_ble_gap_adv_start(&adv_params);
```

• Private address information returned in BLE events

peer IRK.*/

Central connection to peers using private address

```
/* S132 v2.0 API usage */
/* IRK of the Private device. */
ble_gap_irk_t irk1 = { .irk = { 0x10, 0x20, 0x30 /*...*/} };
ble_gap_irk_t * whitelist_irk[1] = {&irk1};
ble_gap_whitelist_t whitelist = {
```

```
.pp_irks = &whitelist_irk, .irk_count = 1,};
ble_gap_scan_params_t scan_params = {
  .selective = true, p_whitelist = &whitelist};
sd_ble_gap_connect(NULL, &scan_params, &conn_params);
```

```
/* S132 v3.0 API usage */
ble_gap_addr_t peer_addr = {
   .addr_id_peer = 1;
   .addr_type = BLE_GAP_ADDR_TYPE_PUBLIC;
   .addr = {0x1A, 0x2A, 0x3A, 0x4A, 0x5A, 0x6A};
}
sd_ble_gap_connect(&peer_addr, &scan_params, &conn_params);
```

LE Ping

The LE ping feature is now supported by the SoftDevice. A new timeout source BLE_GAP_TIMEOUT_SRC_AUTH_PAYLOAD has been added. All applications must handle this event from the SoftDevice according to the API documentation. Refer to the description of LE Ping in the New functionality section for more details.

Required changes:

```
/* S132 v3.0 API usage */
/* Ignore the authenticated payload timeout event */
case BLE_GAP_TIMEOUT_SRC_AUTH_PAYLOAD:
    break;
```

Configurable ATT_MTU

The feature of configurable ATT_MTU is now supported by the SoftDevice. A new event BLE_GATTS_EVT_EXCHANGE_MTU_REQUEST has been added. All applications must handle this event from the SoftDevice according to the API documentation. Refer to the description of configurable ATT_MTU in the New functionality section for more details.

Required changes:

```
/* S132 v3.0 API usage */
/* Respond with default ATT_MTU, if peer initiates an ATT_MTU exchange procedure. */
case BLE_GATTS_EVT_EXCHANGE_MTU_REQUEST:
   sd_ble_gatts_exchange_mtu_reply(p_ble_evt->evt.gatts_evt.conn_handle, GATT_MTU_SIZE_DEFAULT);
   break;
```

New functionality

Configurable ATT_MTU

The Configurable ATT_MTU feature enables the ATT protocol to use packets longer than the default of 23 bytes. This can be useful for example to reduce complexity of GATTC and GATTS procedures used to handle longer Characteristic Value, where a single "Write Request" can be used instead of the whole "Queued Writes" procedure.

API updates

- A new BLE initialization structure, ble_gatt_enable_params_t, has been added to ble_enable_params_t for configuring the maximum ATT_MTU the SoftDevice can send or receive.
- A new SV call, sd_ble_gattc_exchange_mtu_request(), has been added for starting an ATT_MTU exchange.
- A new SV call, $sd_ble_gatts_exchange_mtu_reply()$, has been added for setting the ATT_MTU in ATT_MTU response.
- A new event, BLE_GATTS_EVT_EXCHANGE_MTU_REQUEST, has been added to BLE_GATTS_EVTS to notify that an ATT_MTU request has been received. sd_ble_gatts_exchange_mtu_reply() m ust be called by the application, after this event has been received, to continue the ATT_MTU exchange procedure.
- A new event, BLE_GATTC_EVT_EXCHANGE_MTU_RSP, has been added to BLE_GATTC_EVTS to notify that an ATT_MTU response has been received. This event marks the end of the ATT_MTU exchange procedure and indicates the server ATT_MTU.

Usage

• ATT_MTU exchange can be initiated locally or by peer device.

- HVx and service changed cannot run while a local client initiated ATT_MTU exchange is active. The SV calls sd_ble_gatts_hvx() and sd_ble_gatts_service_changed() will return NRF_ERROR_INVALID_STATE if a local client initiated ATT_MTU exchange is ongoing.
- Following is the pseudo code for case where ATT_MTU exchange is initiated by application:

```
ble_enable_params_t enable_params = {0};
/* Set maximum ATT MTU the SoftDevice can send or receive */
enable_params.gatt_enable_params.att_mtu = 158;
/* Set other BLE Initialization parameters */
/* Enable the BLE Stack */
sd ble enable(&enable params, ...);
[...]
uint16 t conn handle;
/* Establish connection */
[...]
/* Start ATT_MTU exchange */
sd_ble_gattc_exchange_mtu_request(conn_handle, client_rx_mtu);
[...]
uint16 t effective att mtu;
uint16_t server_rx_mtu;
/* Handle the event */
case BLE GATTC EVT EXCHANGE MTU RSP:
  server_rx_mtu = p_ble_evt->evt.gattc_evt.params.exchange_mtu_rsp.server_rx_mtu;
```

LE Ping

The LE Ping feature can be used by the application to configure a link to try to have at least one authenticated packet exchange within a configurable timeout period. If the peer device does not send an authenticated packet within the timeout, a timeout event is generated to notify this to the application.

API updates

- A new GAP option, BLE_GAP_OPT_AUTH_PAYLOAD_TIMEOUT, has been added to set the authenticated payload timeout.
- A new GAP timeout source, BLE_GAP_TIMEOUT_SRC_AUTH_PAYLOAD, has been added to indicate that the authenticated payload timer has expired.

Usage

```
/* Enable the BLE Stack */
[...]
/* Establish connection */
[...]
```

```
/* Authenticated payload timer runs with default value.
Set the authenticated payload timeout for the link, if required to be something else then the default */
gap_opt.auth_payload_timeout.conn_handle = connection_handle;
gap_opt.auth_payload_timeout.auth_payload_timeout = 1000;
gap_opt_set(BLE_GAP_OPT_AUTH_PAYLOAD_TIMEOUT, &gap_opt);
[...]
/* Handle the event */
case BLE_GAP_TIMEOUT_SRC_AUTH_PAYLOAD:
    /* Handling of the event is application dependent. It can be ignored if not used by application. */
break;
```

LE Data Packet Length Extension (DLE)

The LE Data Packet Length Extension feature enables the SoftDevice to use longer packets on the link layer level. Now link layer packets with up to 251 bytes payload are supported.

API updates

- A new GAP option, BLE_GAP_OPT_EXT_LEN, has been added to set the maximum Link Layer PDU length to be used in DLE.
- A new event, BLE_EVT_DATA_LENGTH_CHANGED, has been added to indicate that the Link Layer PDU length has changed.

Usage

- Default max Link Layer PDU is 27 bytes.
- BLE_GAP_OPT_EXT_LEN changes the max length for all future links.
- Example pseudo code:

```
/* Enable the BLE Stack */
[...]
```

```
/* Set max Link Layer PDU length, if application wants it to be more than 27bytes */
gap_opt.ext_len.rxtx_max_pdu_payload_size = 54; //Example: set max length to 54bytes
gap_opt_set(BLE_GAP_OPT_EXT_LEN, &gap_opt);
[...]
/* Establish connection */
[...]
/* Handle the event */
case BLE_EVT_DATA_LENGTH_CHANGED:
    /* Handling of the event is application dependent. It can be ignored if not used by application. */
```

LL Privacy

The LL Privacy feature provides similar functionality as the privacy in the previous version of the SoftDevice. In addition, it supports new use cases like enabling privacy for directed advertising and advanced filter policy for scanning.

API updates

- New SV calls, sd_ble_gap_privacy_set() and sd_ble_gap_privacy_get(), are added to set and get the privacy settings. ble_gap_privacy_params_t is defined to be used with these calls.
- The GAP option BLE_GAP_OPT_PRIVACY is removed. The SV calls sd_ble_gap_privacy_set() and sd_ble_gap_privacy_get() should be used instead.
- A new GAP characteristic, BLE_UUID_GAP_CHARACTERISTIC_CAR, has been added for Central Address Resolution.
- The SV calls sd_ble_gap_address_set() and sd_ble_gap_address_get() have been renamed to sd_ble_gap_addr_set() and sd_ble_gap_addr_get() respectively.
- A new SV call, sd_ble_gap_whitelist_set(), has been added to set the whitelist. The configured whitelist is shared among all BLE roles.
- A new SV call, sd_ble_gap_device_identities_set(), has been added to set the identity list. The configured identity list is shared among all BLE roles.
- New definitions, BLE_GAP_PRIVACY_MODE_OFF and BLE_GAP_PRIVACY_MODE_DEVICE_PRIVACY, have been added.
- Two new GAP error codes, BLE_ERROR_GAP_DEVICE_IDENTITIES_IN_USE and BLE_ERROR_GAP_DEVICE_IDENTITIES_DUPLICATE, have been added.
- Address cycling, BLE_GAP_ADDR_CYCLE_MODE_NONE and BLE_GAP_ADDR_CYCLE_MODE_AUTO, is removed from GAP API sd_ble_gap_addr_set(). Address will always cycle if privacy is enabled by sd_ble_gap_privacy_set().
- New definitions, BLE_GAP_DEFAULT_PRIVATE_ADDR_CYCLE_INTERVAL_S and BLE_GAP_MAX_PRIVATE_ADDR_CYCLE_INTERVAL_S, have been added for address cycle intervals.
- **BLE_GAP_WHITELIST_IRK_MAX_COUNT is renamed to BLE_GAP_DEVICE_IDENTITIES_MAX_COUNT.**
- A new field, addr_id_peer, has been added in the ble_gap_addr_type_t, which indicates an IRK/identity match of a peer.

- ble_gap_whitelist_t is removed because it is not used anymore. This also means that it is removed from ble_gap_adv_params_t and ble_gap_scan_params_t.sd_ble_gap_whitelist_s et() is supposed to be used instead for setting the whitelist.
- ble_gap_scan_params_t is updated. "adv_dir_report" field has been added to enable extended scanner filter policies.
- ble_gap_evt_connected_t is updated. "own address", "irk_match" and "irk_match_index" fields are removed. "irk_match" is now given by "addr_id_peer" fileld in "peer_addr".
- ble_gap_evt_adv_report_t is updated and a new field, "direct_addr", has been added to support extended scanner filter policy.

Usage

• Example pseudo code using the new privacy API:

```
/* Enable the BLE Stack */
[...]
/* Enable privacy */
ble gap privacy params t privacy params = {0};
privacy params.privacy mode = BLE GAP PRIVACY MODE DEVICE PRIVACY;
privacy_params.private_addr_type = BLE_GAP_ADDR_TYPE_RANDOM_PRIVATE_RESOLVABLE;
privacy_params.private_addr_cycle_s = 0; /* Default cycle period will be used. */
privacy_params.p_device_irk = &own_irk;
sd_ble_gap_privacy_set(&privacy_params);
[...]
/* start scanner and get adv report */
[...]
/* Connect to chosen advertiser(advertiser using private address). */
ble gap addr t peer addr = {
  .addr id peer = 0;
  .addr type = BLE_GAP_ADDR_TYPE_RANDOM_PRIVATE_RESOLVABLE;
  .addr = {0xCC, 0xBB, 0xAA, 0xAA, 0xBB, 0xCC};
```

```
sd_ble_gap_connect(&peer_addr, &scan_params, &conn_params);
[...]
/* Perform bonding */
[...]
/* With IRK exchanged, the identity list can be configured to enable address resolution.*/
ble_gap_id_key_t identity = {
  .id_addr_info = {
    .addr_type = BLE_GAP_ADDR_TYPE_PUBLIC,
    .addr = \{0x1A, 0x2A, 0x3A, 0x4A, 0x5A, 0x6A\}, \}
  .id info = {
        .irk = { 0x01, 0x02, 0x03 /*...*/},
};
ble gap id key t * identities[] = { &identity };
sd_ble_gap_identities_set(&identities, NULL, 1);
[...]
/* For all future connections, IRK filtering will be performed. */
ble_gap_addr_t peer_addr = {
  .addr_id_peer = 1;
    .addr_type = BLE_GAP_ADDR_TYPE_PUBLIC,
    .addr = \{0x1A, 0x2A, 0x3A, 0x4A, 0x5A, 0x6A\}
sd ble qap connect(&peer addr, &scan params, &conn params);
[...]
/* It is also possible to use extended filter policy to perform IRK resolution on directed adv reports. */
```

```
ble_gap_scan_params_t scan_params;
scan params.adv dir report = 1;
sd ble gap scan start(&scan params);
[...]
/* Handle the event */
case BLE_GAP_EVT_ADV_REPORT:
/* Adv report will also be generated for directed advertisements where
the initiator field is set to a private resolvable address, even if
 the address did not resolve to an entry in the device identity list.*/
if (ble_evt->adv_report.type == BLE_GAP_ADV_TYPE_ADV_DIRECT IND)
  if (ble_evt->adv_report.direct_addr.addr_type ==
       BLE_GAP_ADDR_TYPE_RANDOM_PRIVATE_RESOLVABLE)
   {
     // The initiator address is not resolved
   else
     // The initiator address is resolved
```

Connection Event Length Extension

This feature can be used to dynamically extend the connection event length when possible to send extra packets compared to the configured bandwidth in a connection interval.

API updates

• A new option, BLE_COMMON_OPT_CONN_EVT_EXT, has been added to BLE_COMMON_OPTS for enabling/disabling of this feature.

Usage

- This feature of dynamic extension of connection event length is disabled by default.
- The **BLE_COMMON_OPT_CONN_EVT_EXT** option can be used to enable/disable this feature. This will result in enabling/disabling this feature for all currently active links and also for all future links.

Full length device name

The maximum possible length of the device name has been increased, and it is now possible to set a device name up to 248 bytes.

API updates

• A new parameter, ble_gap_device_name_t, has been added to sd_ble_enable() for setting full length device name.

Usage

• Example pseudo code:

```
ble_enable_params_t enable_params = {0};

/* Set the device name, if application wants to set anything longer than BLE_GAP_DEVNAME_DEFAULT_LEN */

ble_gap_device_name_t device_name = {0};

uint8_t device_name_buff[BLE_GAP_DEVNAME_MAX_LEN] = "My very long exciting application name";

device_name.vloc = BLE_GATTS_VLOC_STACK; /*Note: Device name will occupy space in Attribute Table.*/

device_name.p_value = device_name_buff;

device_name.max_len = sizeof(device_name_buff);

device_name.current_len = strlen((char *)device_name_buff);

enable_params.gap_enable_params.p_device_name = &device_name;

/* Set other BLE Initialization parameters */

sd_ble_enable(&enable_params, ... );

[...]
```

Max BLE event length calculation

The maximum size of a BLE event can now be calculated to optimize the size of event buffer memory.

API updates

• A new macro, BLE_EVTS_LEN_MAX, has been added to find out the maximum size of BLE events.

Usage

```
/* Old API: */
uint8_t evt[sizeof(ble_evt_t) + BLE_L2CAP_MTU_DEF];
uint16_t evt_len = sizeof(evt);
errcode = sd_ble_evt_get(evt, &evt_len);
```

```
/* New API: */
uint8_t evt[BLE_EVTS_LEN_MAX(GATT_MTU_SIZE_DEFAULT)];
uint16_t evt_len = sizeof(evt);
errcode = sd_ble_evt_get(evt, &evt_len);
```

Other miscellaneous updates

- The SoftDevice Information Structure has been updated and new access macros have been added. Note that this these updates are for Nordic internal use and should not be used by the application.
- New access macros for general purpose retention registers have been added.

API diff

A diff of the API changes between versions s132_nrf52_3.0.0 and s132_nrf5x_2.0.1 is provided with this release. Refer to the file s132_nrf52_3.0.0_API-update.diff.

s13x_nrf5x_2.0.1

This section describes how to migrate to s13x_nrf5x_2.0.1 from s130_nrf51_1.0.0.

Required changes

SoftDevice size

The size of the SoftDevice has changed requiring a change to the application project file.

For Keil this means:

- Go into the properties of the project and find the Target tab
- Change IROM1 Start to 0x1B000 (s130) or 0x1C000 (s132).

If the project uses a scatter file or linker script instead, those must be updated accordingly.

SVC number changes

The SVC numbers in use by the SoftDevice have been changed so the application needs to be recompiled against the new header files.

Fault handling

The SoftDevice has changed the way it handles unrecoverable errors, now known as "faults". SoftDevice assertions were reported to the application in previous releases, now a wider range of faults has been introduced and a new handling mechanism. The new format for the fault handler to be supplied to sd_softdevice_enable() reflects this.

The old

typedef void (*softdevice_assertion_handler_t)(uint32_t pc, uint16_t line_number, const uint8_t * p_file_name);

is now replaced by:

```
typedef void (*nrf_fault_handler_t)(uint32_t id, uint32_t pc, uint32_t info);
```

The application code must now provide a fault handler in the above format. The source of the fault is provided in the fault ID parameter (id) and the value of the program counter at the time of the fault is provided in the program counter parameter (pc). So far the SoftDevice defines the following fault IDs:

- NRF_FAULT_ID_SD_ASSERT: The SoftDevice has triggered an assertion. Record the value of the pc parameter and make it available to the Nordic support team to start an internal investigation.
- (s132 only) NRF_FAULT_ID_APP_MEMACC: The application has triggered an unallowed memory access. The value of the pc parameter will contain the address of the instruction that executed the invalid memory access, or the address of the instruction following the violation. To find out the filename and line number within your application source code that correspond to the pc you can use the appropriate tool provided with your toolchain. For example if your linker outputs files in the ELF format you can use the addr2line tool which is part of the GNU ARM Embedded toolchain for this purpose. Note that you don't need to have compiled with GCC to use addr2line, and that there are several common filename extensions for ELF files, e.g. .elf, and .axf.

```
// Syntax
arm-none-eabi-addr2line <pc> -e application.elf
// Example, pc=0x01da6a
$ arm-none-eabi-addr2line 0x01da6a -e app_beacon.elf
C:\dev\app_beacon\src\main.c:34
```

Please note that as part of this transition from asserts to faults the previously distributed softdevice_assert.h file is no longer part of the public API.

Oscillator configuration

The configuration of the 32 kHz RCOSC calibration in sd_softdevice_enable() has been made more flexible. It now supports more calibration intervals, and the ability to combine temperature and time triggered calibration.

sd_softdevice_enable(nrf_clock_lf_cfg_t const * p_clock_lf_cfg, nrf_fault_handler_t fault_handler));

```
// Example configuration equivalent to the old NRF_CLOCK_LFCLKSRC_RC_250_PPM_TEMP_1000MS_CALIBRATION
nrf_clock_lf_cfg_t rc_cfg = {
    .source = NRF_CLOCK_LF_SRC_RC,
    .rc_ctiv = 4, // Check temperature every 4 * 250ms
    .rc_temp_ctiv = 1, // Only calibrate if temperature has changed.
};
sd_softdevice_enable(&rc_cfg, &app_fault_handler);
// Example configuration equivalent to the old NRF_CLOCK_LFCLKSRC_XTAL_75_PPM
nrf clock lf cfg t xtal cfg = {
```

```
.source = NRF_CLOCK_LF_SRC_XTAL,
.xtal_accuracy = NRF_CLOCK_LF_XTAL_ACCURACY_75_PPM
};
sd_softdevice_enable(&xtal_cfg, &app_fault_handler);
// Recommended configuration for using the RC oscillator with s132 (see nrf_sdm.h for details)
nrf_clock_lf_cfg_t rc_cfg = {
    .source = NRF_CLOCK_LF_SRC_RC,
    .rc_ctiv = 16, // Check temperature every 4 seconds
    .rc_temp_ctiv = 2, // Calibrate at least every 8 seconds even if the temperature hasn't changed
};
sd_softdevice_enable(&rc_cfg, &app_fault_handler);
```

App priorities

The enumeration NRF_APP_PRIORITIES has been removed. Application developers must use the interrupt priority levels directly instead.

For s130 the interrupt priority levels available to the application are: 1 and 3.

For s132 the interrupt priority levels available to the application are: 2, 3, 6 and 7.

SEVONPEND flag and high interrupt priorities

Applications must not modify the SEVONPEND flag in the SCR register when running in priority level 1 for s130 and priority levels 2 or 3 for s132.

Type definitions

Type definitions for certain basic types have been removed. The following type definitions must be replaced with uint8_t:

nrf_power_mode_t, nrf_power_failure_threshold_t, nrf_radio_notification_distance_t, nrf_radio_notification_type_t

and the following must be replaced with uint32_t:

nrf_app_irq_priority_t nrf_power_dcdc_mode_t

MBR size

The macro MBR_SIZE has been moved to nrf_mbr.h.

Changes to the sd_nvic_* API

The sd_nvic_* API functions have changed from being SV calls into the SoftDevice to being static functions implemented in a new header file, nrf_nvic.h. This header file must be included in all source files that call any API function than begins with sd_nvic_. If a project includes nrf_nvic.h in any of its source files, one of them must declare and zero initialize a global instance of nrf_nvic_state_t in the form:

nrf_nvic_state_t nrf_nvic_state = {0};

Flash protection

The flash protection API now takes 4 parameters, only the first 2 of which are applicable for the s130:

sd_flash_protect(uint32_t block_cfg0, uint32_t block_cfg1, uint32_t block_cfg2, uint32_t block_cfg3);

Radio Timeslot API macro changes

The macros for high frequency clock configuration have been renamed in the Radio Timeslot API:

- NRF_RADIO_HFCLK_CFG_DEFAULT and NRF_RADIO_HFCLK_CFG_FORCE_XTAL
- are now NRF_RADIO_HFCLK_CFG_XTAL_GUARANTEED and NRF_RADIO_HFCLK_CFG_NO_GUARANTEE

The default is now NRF_RADIO_HFCLK_CFG_XTAL_GUARANTEED which guarantees that the high frequency clock source is the crystal for the whole duration of the timeslot. This should be the preferred option for events that use the radio or require high timing accuracy.

SoftDevice runtime configuration

The number of Vendor Specific UUIDs, connection count and bandwidth are now configurable on sd_ble_enable() using the new parameters in the substructures of ble_enable_params_t. Those new parameters are listed below:

- vs_uuid_count: The number of Vendor Specific UUID bases that the SoftDevice will reserve space for. Formerly this number was fixed and set to BLE_UUID_VS_MAX_COUNT.
- p_conn_bw_counts: The optional connection bandwidth configuration structure. This determines the amount of memory that the SoftDevice will reserve for packets. See the bandwidth configuration section for more details.
- periph_conn_count: The total amount of concurrent connections as a peripheral that will be available to the application.
- central_conn_count: The total amount of concurrent connections as a central that will be available to the application.

• central_sec_count: The total amount of concurrent pairing procedures that will be available to the application to be shared among all connections as a central.

If the maximum number of connections supported by the SoftDevice is exceeded in the call to sd_ble_enable() the SoftDevice will return NRF_ERROR_CONN_COUNT.

SoftDevice RAM usage

At runtime the IC's RAM is split into 2 regions: The SoftDevice RAM region (between 0x2000000 and APP_RAM_BASE-1) and the application RAM region (between APP_RAM_BASE and the call stack). The start address of the application RAM region (APP_RAM_BASE) is dependent on the configuration provided to the SoftDevice in the call to sd_ble_enable().

The sd_ble_enable() call has a new parameter.

- uint32_t sd_ble_enable(ble_enable_params_t * p_ble_enable_params)
- uint32_t sd_ble_enable(ble_enable_params_t * p_ble_enable_params, uint32_t * p_app_ram_base)

The new *p_app_ram_base parameter should be set by the application to APP_RAM_BASE. The SoftDevice will return the minimum APP_RAM_BASE required by the SoftDevice for the configuration. If the APP_RAM_BASE provided by the application is smaller than the APP_RAM_BASE returned by the SoftDevice, sd_ble_enable() will return NRF_ERROR_NO_MEM.

Note: The nRF5 SDK provides definitions for common configurations and several toolchains. You can skip the rest of this section if you plan to use the nRF5 SDK examples directly and do not intend to create new configurations.

The application must **always** provide the current starting address of its RAM area (as defined in the project file, scatter file or linker script) as the *p_app_ram_base parameter to sd_ble_enable(). Failure to do so might result in the SoftDevice overwriting the application memory area and/or memory access violations. Most toolchains provide a linker symbol for the starting address of their RAM area, referred to as _______ LINKER_APP_RAM_BASE in this documentation.

The following table shows examples of linker symbols that can define __LINKER_APP_RAM_BASE for different toolchains. The actual value will depend on the project file, scatter file or linker script settings.

Toolchain	LINKER_APP_RAM_BASE
ARMCC/Keil	Image\$\$RW_IRAM1\$\$Base
IAR	ICFEDIT_region_RAM_start
GCC	data_start

The recommended approach to obtaining and maintaining the required APP_RAM_BASE for the application is the following:

1. In your project file, scatter file or linker script, set the starting address of your application's RAM (APP_RAM_BASE) to at least the minimum APP_RAM_BASE specified in the release notes.

- 2. In your application's source code, set the value of *p_app_ram_base to __LINKER_APP_RAM_BASE.
- 3. Set the desired parameters to be provided to sd_ble_enable().
- 4. Compile, link and run the application.

- 5. If the amount of memory assigned to the SoftDevice by *p_app_ram_base is large enough to fit the configuration, sd_ble_enable() will return NRF_SUCCESS, otherwise it will return NRF_ERROR_NO _MEM.
- 6. On return of sd_ble_enable(), *p_app_ram_base will contain the APP_RAM_BASE required for the given configuration.
- 7. In your project file, scatter file or linker script, update the starting address of your application's RAM (APP_RAM_BASE) to *p_app_ram_base from step 6, and recompile the application.

Please note that it is possible to run the application with APP_RAM_BASE set higher than the minimum required by the selected configuration. Doing so will result in an area of memory being unused located between the SoftDevice's and the application's memory areas.

Enabling the BLE Stack		
ble_enable_params_t params;		
uint32_t retv;		
uint32_t app_ram_base;		
<pre>memset(&params, 0x00, sizeof(params));</pre>		
/* set the number of Vendor Specific UUIDs to 5 */		
params.common_enable_params.vs_uuid_count = 5;		
/* this application requires 1 connection as a peripheral */		
<pre>params.gap_enable_params.periph_conn_count = 1;</pre>		
/* this application requires 3 connections as a central */		
<pre>params.gap_enable_params.central_conn_count = 3;</pre>		
/* this application only needs to be able to pair in one central link at a time */		
<pre>params.gap_enable_params.central_sec_count = 1;</pre>		
/* we require the Service Changed characteristic */		
<pre>params.gatts_enable_params.service_changed = 1;</pre>		
/* the default Attribute Table size is appropriate for our application */		
params.gatts_enable_params.attr_tab_size = BLE_GATTS_ATTR_TAB_SIZE_DEFAULT;		
/* set app_ram_base to the starting memory address of the application RAM,		
obtained directly from the linker */		
app_ram_base =LINKER_APP_RAM_BASE;		
/* enable the BLE Stack */		
retv = sd_ble_enable(¶ms, &app_ram_base);		
if(retv == NRF_SUCCESS)		

```
{
        /* Verify that LINKER APP RAM BASE matches the SD calculations */
        if (app ram base != LINKER APP RAM BASE)
                /* The application's starting RAM address is higher than the one required for this
configuration.
                   An area of memory will remain unused between the SoftDevice and the application memory areas.
           To detect this, place a breakpoint here and/or output (app ram base)
           through a debug interface.
                 */
        }
else if(retv == NRF_ERROR_NO_MEM)
        /* The application's starting RAM address is lower than the one required for this configuration.
       This is an unrecoverable error because the SoftDevice and the application memory areas overlap.
       To detect this, place a breakpoint here and/or output (app ram base)
       through a debug interface.
        * /
        while(1){}
```

Default Attribute Table size changed

The default Attribute Table size has gone down from 0x600 bytes to 0x580 bytes. If the application is not setting a custom Attribute Table size and it is filling it completely, it will now need to configure a larger, non-default memory area size dedicated to it (ble_gatts_enable_params_t::attr_tab_size) in the call to sd_ble_enable().

(s130 only) CPU and Radio mutual exclusion option removed

The <u>BLE_COMMON_OPT_RADIO_CPU_MUTEX</u> option is no longer part of the SoftDevice API so applications making use of it will need to remove all code using it. The option is no longer necessary since this version of the SoftDevice is only compatible with IC revision 3 of the nRF51 series, which no longer requires mutual exclusion between the radio and the CPU during operation.

TX packet management

The user TX packet management has been modified to adapt it to the fact that different connections can now make different packet counts available to the application, depending on the role and bandwidth configuration. This means that the application now needs to obtain the TX packet count **after** each connection is established, and needs also to keep an independent variable for the TX packet count of each connection.

The prototype has been therefore renamed and adapted:

- uint32_t sd_ble_tx_buffer_count_get(uint8_t *p_count)
- uint32_t sd_ble_tx_packet_count_get(uint16_t conn_handle, uint8_t *p_count)

Here's an example of an application obtaining the TX packet count for a particular connection and storing it in a global variable for later use:

```
case BLE_GAP_EVT_CONNECTED:
    uint8_t count;
    uint16_t conn_handle = p_ble_evt->evt.gap_evt.conn_handle;
    sd_ble_tx_packet_count_get(conn_handle, &count);
    /* store TX packet count for later use */
    tx_packet_counts[conn_handle] = count;
    break;
```

TX power setting

The sd_ble_gap_tx_power_set() SV call now accepts the following values as the lowest power setting:

- s130: -30dBm
- s132: -40dBm

If the application code made use of values different from those in its minimum power output mode it will have to be adapted it to conform with the changes.

Additional link field in the key distribution bitfield

The ble_gap_sec_kdist_t bitfield now includes an additional link bit. This must always be set to 0 by the application since it is only intended for use with dual-mode BR/EDR+BLE solutions.

Additional lesc field in the encryption information structure

A new lesc bit has been added to the ble_gap_enc_info_t structure. It is important to initialize this bit correctly when loading stored security keys, so that the SoftDevice can set the connection's security level accordingly.

Additional fields in the security parameters

Two new fields have been added to ble_gap_sec_params_t:

- lesc: This enables LE Secure Connections locally when starting a pairing or bonding procedure. If the application does not wish to use LE Secure Connections and instead use legacy pairing simply set this bit to 0.
- keypress: This enables keypress notifications locally when starting a pairing or bonding procedure. Keypress notifications can be used whenever the Passkey Entry pairing method is selected, both in legacy pairing or LE Secure Connections.

Both fields need to be initialized to the desired value by applications transitioning to this SoftDevice version.

Security keys identification by locality instead of by GAP role

The security keys included in ble_gap_sec_keyset_t are no longer identified by GAP role, but rather by associating them with the local device (own) or with the remote device (peer):

- ble_gap_sec_keyset_t::keys_periph and ble_gap_sec_keyset_t::keys_central are now expressed in terms of ble_gap_sec_keyset_t::keys_own and ble_gap_sec_keyset_t::keys_peer
- ble_gap_sec_params_t::kdist_periph and ble_gap_sec_params_t::kdist_central are now expressed in terms of ble_gap_sec_params_t::kdist_own and ble_gap_sec_params_t::kdist_peer
- ble_gap_evt_auth_status_t::kdist_periph and ble_gap_evt_auth_status_t::kdist_central are now expressed in terms of ble_gap_evt_auth_status_t::kdist_own and ble __gap_evt_auth_status_t::kdist_peer

For example, a multi-role application wanting to distribute its own LTK when acting as a peripheral, but only its IRK when acting as a central and that always accepts IRKs from the peer no matter the role:

```
/* Connected */
if(own_role == BLE_GAP_ROLE_PERIPH)
{
    sec_params.kdist_own.enc = 1;
}
else /* BLE_GAP_ROLE_CENTRAL */
{
    sec_params.kdist_own.id = 1;
}
sec_params.kdist_peer.id = 1;
```

Identity key distribution change

When distributing Identity keys during a bonding procedure, the handling of the pointers within the ble_gap_sec_keyset_t structure has changed in the following manner:

- Setting ble_gap_sec_keyset_t::keys_own::p_id_key to NULL remains unchanged: the stack will continue to make use of the currently set Bluetooth address and IRK and distribute them to the peer, but the application will not receive a copy in its memory
- Setting ble_gap_sec_keyset_t::keys_own::p_id_key to a valid pointer to a location in the application memory will distribute the same Bluetooth address and IRK as above (the currently set ones) and also make them available to the application

That means that if the application distributed a custom Bluetooth address and IRK using the following deprecated functionality:

```
/* Connected */
keyset.keys_own.p_id_key = &app_custom_id_key;
keyset.keys_own.p_id_addr_info = &custom_bdaddr;
sd_ble_gap_sec_params_reply(conn_handle, BLE_GAP_SEC_STATUS_SUCCESS, &sec_params, &keyset);
```

it will now have to manually set those before calling sd_ble_gap_sec_params_reply():

```
/* Connected */
ble_opt_t opt;
sd_ble_gap_address_set(BLE_GAP_ADDR_CYCLE_MODE_NONE, &app_custom_id_key.id_addr_info);
opt.gap_opt.privacy.p_irk = &app_custom_id_key.id_info;
opt.gap_opt.privacy.interval_s = APP_ADDR_REFRESH_S;
sd_ble_opt_set(BLE_GAP_OPT_PRIVACY, &opt);
keyset.keys_own.p_id_key = &distributed_id_key;
sd_ble_gap_sec_params_reply(conn_handle, BLE_GAP_SEC_STATUS_SUCCESS, &sec_params, &keyset);
```

GATT Server Read/Write events: attribute context removed

The ble_gatts_attr_context_t type has been removed from the GATT Server API. The two structures that included an instance of it as a member now include instead a ble_uuid_t instance to identify the attribute:

- ble_gatts_evt_write_t::context has been replaced by ble_gatts_evt_write_t::uuid
- ble_gatts_evt_read_t::context has been replaced by ble_gatts_evt_read_t::uuid

In practical usage most applications store the handles associated with a particular characteristic when populating the Attribute Table. Calculating the context for each incoming read or write operation was an expensive and time-consuming task, and therefore the field has been removed and instead replaced by the attribute UUID. The combination of attribute handle and attribute UUID provided in the event structure should be enough for the application to identify the attribute within the set that has been previously populated.

GATT Server Authorizable Write Commands

Whenever the application enables write authorization for a characteristic value or a descriptor in the Attribute Table (ble_gatts_attr_md_t::wr_auth), all incoming write operations will now require application authorization. In particular this now includes Write Commands (also called Write Without Response) which will arrive in the same event form (BLE_GATTS_EVT_WRITE) but with a new field set (ble_g atts_evt_write_t::auth_required) to indicate to the application that the data has not been written into the Attribute Table. Upon handling of the event the application can decide whether it wants to write the incoming data to the Attribute Table using sd_ble_gatts_value_set() or discard it.

	Handling incoming authorizable Write Commands
ase BLE_GATTS_	_EVT_WRITE:
uint16_	_t conn_handle = p_ble_evt->evt.gatts_evt.conn_handle;
uint16_	_t attr_handle = p_ble_evt->evt.gatts_evt.params.write.handle;
uint16_	_t offset = p_ble_evt->evt.gatts_evt.params.write.offset;
uint8_1	t *p_data = p_ble_evt->evt.gatts_evt.params.write.data;
uint16_	_t dlen = p_ble_evt->evt.gatts_evt.params.write.len;
if(p_b]	le_evt->evt.gatts_evt.params.write.auth_required)
{	
,	/* incoming write command on an attribute requiring authorization,
val	idate the incoming data pointed to by p_data */
	if(app_data_authorize(p_data, offset, dlen))
/*	the application manually writes the incoming data (p_data) to the Attribute Table */
	ble_gatts_value_t value;
	value.len = dlen;
	value.offset = offset;
	value.p value = p data;
	sd_ble_gatts_value_set(conn_handle, attr_handle, &value);
	}
}	ſ
, break;	

GATT Server Write Authorization and peer data

Applications making use of authorization to handle incoming write operations, and in particular Write Requests and app-handled Queued Writes, will now have to store the incoming data to be provided later to the SoftDevice. Depending on how the application handles the authorization procedure, this can be done by providing the same pointer contained in the event field, or copying the data into a temporary storage area if required.

• Authorizing directly in the event handler:

```
case BLE GATTS EVT RW AUTHORIZE REQUEST:
        if(p ble evt->evt.gatts evt.params.authorize request.type == BLE GATTS AUTHORIZE TYPE WRITE)
                uint16 t conn handle = p ble evt->evt.gatts evt.conn handle;
                uint16 t offset = p ble evt->evt.gatts evt.params.authorize request.request.write.offset;
                uint16_t dlen = p_ble_evt->evt.gatts_evt.params.authorize_request.request.write.len;
                uint8 t *p data = p ble evt->evt.gatts evt.params.authorize request.request.write.data;
                /* incoming write command on an attribute requiring authorization, validate the data */
                if(app data authorize(p data, offset, dlen))
                        ble gatts rw authorize reply params t auth reply;
                        auth reply.type = BLE GATTS AUTHORIZE TYPE WRITE;
                        auth reply.params.write.gatt status = BLE GATT STATUS SUCCESS;
                        auth_reply.params.write.update = 1;
                        auth reply.params.write.offset = offset;
                        auth_reply.params.write.len = dlen;
            /* reuse the same pointer obtained from the event */
                        auth reply.params.write.p data = p data;
                        sd ble gatts rw authorize reply(conn handle, &auth reply);
        break;
```

• Authorizing outside of the event handler:

```
/* global variable storing the authorization data */
struct
       uint16 t conn handle;
        uint16 t offset;
       uint16_t dlen;
       uint8_t data[MAX_DATA];
} auth_write;
[..]
case BLE GATTS EVT RW AUTHORIZE REQUEST:
        if(p ble evt->evt.gatts evt.params.authorize request.type == BLE GATTS AUTHORIZE TYPE WRITE)
                /* store the metadata */
                auth write.conn handle = p ble evt->evt.gatts evt.conn handle;
                auth_write.offset = p_ble_evt->evt.gatts_evt.params.authorize_request.request.write.offset;
                auth_write.dlen = p_ble_evt->evt.gatts_evt.params.authorize_request.request.write.len;
                /* store the actual incoming data */
                memcpy(&auth_write.data, &p_ble_evt->evt.gatts_evt.params.authorize_request.request.write.data,
auth write.dlen);
        break;
[..]
/* authorization complete */
ble_gatts_rw_authorize_reply_params_t auth_reply;
```

```
auth_reply.type = BLE_GATTS_AUTHORIZE_TYPE_WRITE;
auth_reply.params.write.gatt_status = BLE_GATT_STATUS_SUCCESS;
auth_reply.params.write.update = 1;
/* obtain the data */
auth_reply.params.write.offset = auth_write.offset;
auth_reply.params.write.len = auth_write.dlen;
auth_reply.params.write.p_data = auth_write.data;
```

sd_ble_gatts_rw_authorize_reply(auth_write.conn_handle, &auth_reply);

New functionality

Configurable bandwidth

The connections can now be configured to have low, medium or high bandwidth. This can be specified for both TX and RX independently to allow for asymmetric bandwidth. This is an optional feature and if the application chooses not to use it the SoftDevice will instead configure the connections with defaults. The default configuration for connections as a central is BLE_CONN_BW_MID (both for TX and RX), and for connections as a peripheral it is BLE_CONN_BW_HIGH (both for TX and RX).

When using the configurable bandwidth option the application should have specified beforehand, at BLE stack initialization time, a set of connection bandwidth configurations that includes the ones that it intends to use through this option. Once a bandwidth configuration for a particular role is chosen through the sd_ble_opt_set() SV call, all connections of that role established from that time on will use the chosen configuration until a new one is set.

Additional information about this topic can be found in the SoftDevice Specification at http://infocenter.nordicsemi.com/.

The following table shows an approximate comparison of connections and bandwidth configuration for previous SoftDevices as well as the the s13x v2.0.1 configured as shown in the example below.

	connections as a peripheral		connections as a central		
	number	RX / TX bandwith	number	RX / TX bandwith	
s110 v8.0	1	HIGH / HIGH	0	-	
s120 v2.1 (peripheral mode)	1	HIGH / HIGH	0	-	
s120 v2.1 (central mode)	0	-	8	LOW / LOW	
s130 v1.0	1	MID / MID	3	LOW / LOW	
s13x v2.0.1 (default)	0	HIGH / HIGH	0	MID / MID	

s13x v2.0.1 (example configuration below) 1 MID / MID 1 HIGH / MID

```
/* Example for one medium-bandwidth RX and TX connection as a peripheral and high-bandwidth RX, medium-bandwidth
TX connection as a central. */
ble_conn_bw_counts_t conn_bw_counts = {
  .tx counts = {.high count = 0, .mid count = 2, .low count = 0},
  .rx_counts = {.high_count = 1, .mid_count = 1, .low_count = 0}
};
ble enable params t enable params = \{0\};
enable params.common enable params.p conn bw counts = & conn bw counts;
enable params.gap enable params.central conn count = 1;
enable_params.gap_enable_params.periph_conn_count = 1;
sd_ble_enable(&enable_params, ...);
ble_opt_t ble_opt;
/* Configure bandwidth and connect as a peripheral */
ble_common_opt_conn_bw_t conn_bw = { .role = BLE_GAP_ROLE_PERIPH, .conn_bw = { .conn_bw_rx = BLE_CONN_BW_MID, .
conn bw tx = BLE CONN BW MID } ;
ble_opt.common_opt.conn_bw = conn_bw;
sd_ble_opt_set(BLE_COMMON_OPT_CONN_BW, &ble_opt);
sd ble gap adv start( ... );
/* Connection established with the configured bandwidth */
/* Configure bandwidth and connect as a central */
ble_common_opt_conn_bw_t conn_bw = { .role = BLE_GAP_ROLE_CENTRAL, .conn_bw = { .conn_bw_rx = BLE_CONN_BW_HIGH, .
conn bw tx = BLE CONN BW MID } };
ble opt.common opt.conn bw = conn bw;
```

```
sd_ble_opt_set(BLE_COMMON_OPT_CONN_BW, &ble_opt);
sd_ble_gap_connect( ... );
/* Connection established with the configured bandwidth */
```

Block encryption

The blocking block encryption SV call sd_ecb_block_encrypt() depends on the hardware encryption block and therefore will require to wait for it to complete before it returns to the application. If the user now sets the SEVONPEND bit in the SCR to 1 before calling this function, the SoftDevice will sleep while the ECB is running instead of entering a busy loop.

A second SV call has also been introduced to perform multiple block encrypt operations in a single SV call to avoid the context switch overhead when more than one block of data needs to be encrypted.

uint32_t sd_ecb_blocks_encrypt(uint8_t block_count, nrf_ecb_hal_data_block_t * p_data_blocks);

sd_ecb_blocks_encrypt() example usage
/* global variable storing the authorization data */
nrf_ecb_hal_data_block_t blocks[ECB_BLOCK_COUNT];
/* intialize data blocks */
<pre>for(i = 0; i < ECB_BLOCK_COUNT; i++)</pre>
{
<pre>blocks[i].p_key = &app_keys[i];</pre>
<pre>blocks[i].p_cleartext = &app_cleartext[i];</pre>
<pre>blocks[i].p_ciphertext = &app_dest[i];</pre>
}
sd_ecb_blocks_encrypt(ECB_BLOCK_COUNT, blocks);

PA/LNA support

A new BLE option, BLE_COMMON_OPT_PA_LNA, and its corresponding option structure, ble_common_opt_pa_lna_t, have been added to provide support for power amplifiers and low noise amplifiers. The application is responsible for correctly initializing the option parameter structure with the required fields that map to the hardware design:

- PA and LNA pins and active level
- Set and Clear PPI channel IDs
- GPIOTE channel ID

```
PA/LNA option usage
/* PA/LNA configuration */
ble opt t pa lna opt = {
  .common_opt = {
    .pa_lna = {
      .pa cfg = {
       .enable
                = 1,
       .active high = 1,
        .qpio pin = APP PA PIN /* GPIO connected to the PA control pin */
      },
      .lna cfg = {
       .enable
                   = 1,
       .active high = 1,
       .qpio pin = APP LNA PIN /* GPIO connected to the LNA control pin */
      },
      .ppi_ch_id_set = APP_AMP_PPI_CH_ID_SET, /* PPI channel the app gives the SD to set the pins */
      .ppi ch id clr = APP AMP PPI CH ID CLR, /* PPI channel the app gives the SD to clear the pins */
      .qpiote ch id = APP AMP GPIOTE CH ID /* GPIOTE channel the app gives the SD to control the pins */
};
sd ble opt set(BLE COMMON OPT PA LNA, &pa lna opt);
```

LE Secure Connections

Version 4.2 of the Bluetooth Specification introduced a new mode of operation for the Security Manager Protocol, which enables the use of Public Key Cryptography for the generation of security keys. This means that applications can now select the mode of operation of the Security Manager when performing a pairing or bonding procedure:

- Legacy pairing: Set the lesc bit in ble_gap_sec_params_t to 0.
- LE Secure Connections: Set the lesc bit in ble_gap_sec_params_t to 1.

Please note that, in order for LE Secure Connections to be used, the peer will need to support it. If not, legacy pairing will be used by default.

The SoftDevice implements the Security Manager Protocol and cryptographic toolbox functionality required to enable LE Secure Connections, but it does **not** include the Elliptic Curve Cryptography (ECC) methods required to generate public keys and shared secrets. This means that applications must include their own implementation of ECC. The SoftDevice never requires knowledge of the application's private key, since it delegates the calculation of the shared secret (DHKey) to the application itself:

- ble_gap_sec_keys_t::p_pk (*own* only) is provided by the application and represents the P-256 public key (PK_{own}) that matches the local private key (SK_{own}). The key is provided as a part of the bl e_gap_sec_keyset_t structure when calling sd_ble_gap_sec_params_reply().
- BLE_GAP_EVT_LESC_DHKEY_REQUEST is a new event requesting the application to calculate the shared secret, which is the result of P256(SK_{own}, PK_{peer}). The event structure contains the peer's

public key (PK_{peer}) so that the application can start the calculation of the DHKey. Once the application has completed the calculation it must communicate the result to the SoftDevice by using the new sa _ble_gap_lesc_dhkey_reply() SV call.

Additional API changes introduced by LE Secure Connections:

- ble_gap_evt_passkey_display_t now contains an additional field, match_request, used for the new Numeric Comparison pairing algorithm
- sd_ble_gap_auth_key_reply() now accepts BLE_GAP_AUTH_KEY_TYPE_PASSKEY coupled with a NULL p_key pointer to indicate a match in the new Numeric Comparison pairing algorithm
- sd_ble_gap_lesc_oob_data_get() and sd_ble_gap_lesc_oob_data_set() have been introduced to support the new LE Secure Connections OOB pairing method, which is substantially different from the Legacy OOB version

Additional details can be found in the API documentation and the Message Sequence Charts (MSCs) included with the SoftDevice.

Passkey entry keypress notifications

During pairing procedures using the Passkey Entry pairing algorithm (both in Legacy and LE Secure Connections modes) it is now possible to provide feedback to the peer regarding the keypresses being input by the user. The actual value of the keypresses is never sent over the air, but the notifications can be sent to provide visual feedback of the keys being pressed.

To enable the application to send keypress notifications to the peer, the following SV call has been introduced:

• sd_ble_gap_keypress_notify(uint16_t conn_handle, uint8_t kp_not)

Where kp_not maps to any of the values present in the BLE_GAP_KP_NOT_TYPES enumeration.

Sending keypress notifications
/* Pairing procedure using the Passkey Entry algorithm in progress, local device inputs passkey */
/* User starts entering the passkey */
sd_ble_gap_keypress_notify(conn_handle, BLE_GAP_KP_NOT_TYPE_PASSKEY_START);
/* User inputs digits */
sd_ble_gap_keypress_notify(conn_handle, BLE_GAP_KP_NOT_TYPE_PASSKEY_DIGIT_IN);
sd_ble_gap_keypress_notify(conn_handle, BLE_GAP_KP_NOT_TYPE_PASSKEY_DIGIT_IN);
/* User deletes a digit */
sd_ble_gap_keypress_notify(conn_handle, BLE_GAP_KP_NOT_TYPE_PASSKEY_DIGIT_OUT);
/* User clears the input completely */
sd_ble_gap_keypress_notify(conn_handle, BLE_GAP_KP_NOT_TYPE_PASSKEY_CLEAR);
/* User ends the input procedure */
sd_ble_gap_keypress_notify(conn_handle, BLE_GAP_KP_NOT_TYPE_PASSKEY_END);

Please note that sd_ble_gap_keypress_notify() can return NRF_ERROR_BUSY if the application calls it too often and the previous keypress notification has not made it over the air to the peer yet. In that case the application should queue the keypresses internally and retry at a later time.

A new event has also been added to allow the application to receive keypress notifications from the peer:

• BLE_GAP_EVT_KEY_PRESSED and its corresponding ble_gap_evt_key_pressed_t

Receiving keypress notifications

/* Pairing procedure using the Passkey Entry algorithm in progress, peer device inputs passkey */

```
/* handle the event */
case BLE_GAP_EVT_KEY_PRESSED:
    switch(p_ble_evt->evt.gap_evt.params.key_pressed.kp_not)
    {
    case BLE GAP KP NOT TYPE PASSKEY START:
```

```
/* Remote user has started entering the passkey */
    break;
case BLE_GAP_KP_NOT_TYPE_PASSKEY_DIGIT_IN:
    /* Remote user has input a digits */
    break;
case BLE_GAP_KP_NOT_TYPE_PASSKEY_DIGIT_OUT:
    /* Remote user has deleted a digit */
    break;
case BLE_GAP_KP_NOT_TYPE_PASSKEY_CLEAR:
    /* Remote user has cleared the input completely */
    break;
case BLE_GAP_KP_NOT_TYPE_PASSKEY_END:
    /* Remote user has ended the input procedure */
    break;
}
```

Security Mode 1 Level 4

A new security level has been introduced along with support for LE Secure Connections. Security levels are used in GAP and GATT Server to define the connection's security level and the access requirements for the peer to read and write attributes in the local Attribute Table. The list of supported security levels is now:

- Security Mode 0, Level 0: No access allowed regardless of the connection's security level
- Security Mode 1, Level 1: No encryption. The peer can read and write the attribute without restrictions
- Security Mode 1, Level 2: Encryption without MITM protection. Access to the attribute requires an encrypted connection (Legacy or LE Secure Connections) with or without MITM protection
- Security Mode 1, Level 3: Encryption with MITM protection. Access to the attribute requires an encrypted connection (Legacy or LE Secure Connections) with MITM protection
- Security Mode 1, Level 4: LESC Encryption with MITM protection. Access to the attribute requires an encrypted connection (LE Secure Connections only) with MITM protection

To honour the new security level (Security Mode 1, Level 4) encryption must be enabled with an LTK that has been generated during a pairing or bonding procedure using LE Secure Connections with MITM protection (Numeric Comparison, Passkey Entry or OOB). This is the highest security level available when defining the access requirements (permissions) of attributes in the local Attribute Table.

A new macro has been made available to set ble_gap_conn_sec_mode_t to the new security level:

BLE_GAP_CONN_SEC_MODE_SET_LESC_ENC_WITH_MITM

An additional Advertising Data type has been added to ble_gap.h

BLE_GAP_AD_TYPE_URI

GATT Client attribute info discovery

A new SV call allows applications to obtain basic attribute information from the peer's Attribute Table:

uint32_t sd_ble_gattc_attr_info_discover(uint16_t conn_handle, ble_gattc_handle_range_t const * p_handle_range);

the matching event identifier and structure are also part of this new feature:

• BLE_GATTC_EVT_ATTR_INFO_DISC_RSP

- ble_gattc_attr_info_t
- ble_gattc_evt_attr_info_disc_rsp_t

This is the only GATT Client function that allows the application to retrieve full 128-bit UUIDs that do **not** need to be part of the list populated with sd_ble_vs_uuid_add(). An example of 128-bit UUID retrieval is shown below.

```
/* Obtain the attribute handle and the full 128-bit UUID */
    attr_handle= p_ble_evt->evt.gattc_evt.params.attr_info_disc_rsp.attr_info[0].handle;
    memcpy(&uuid128, &p_ble_evt->evt.gattc_evt.params.attr_info_disc_rsp.attr_info[0].info.uuid128.
uuid128, sizeof(uuid128));
    }
    break;
```

GATT Server first user attribute handle retrieval

When using the Service Changed characteristic to indicate to the peer that the local Attribute Table structure has changed, it is often useful to find out at which handle the application-controlled region of the Attribute Table begins. For that specific purpose a new SV call has been introduced:

uint32_t sd_ble_gatts_initial_user_handle_get(uint16_t *p_handle);

This allows the application to communicate to the peer the exact range of the attributes that require rediscovery.

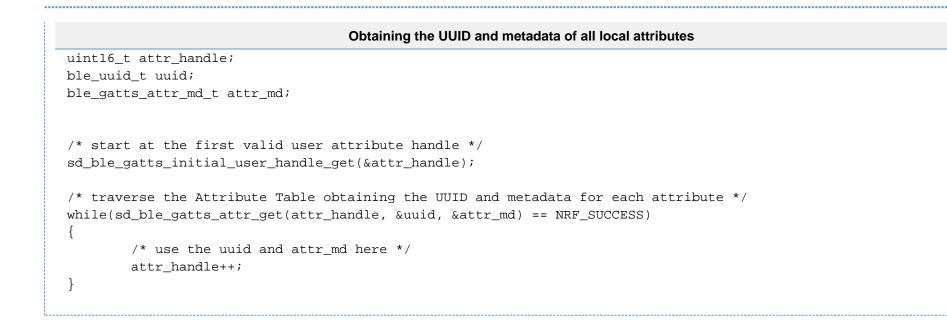

Obtaining the first user handle to indicate a Service Changed uint16_t first_attr_handle; sd_ble_gatts_initial_user_handle_get(&first_attr_handle); sd_ble_gatts_service_changed(conn_handle, first_attr_handle, last_affected_handle);

GATT Server local attribute metadata retrieval

The GATT Server module has always allowed applications to retrieve the value of any attribute present in the local Attribute Table by means of the sd_ble_gatts_value_get() SV call. Now in addition applications can also retrieve the UUID and metadata of any local attribute using the new function:

uint32_t sd_ble_gatts_attr_get(uint16_t handle, ble_uuid_t * p_uuid, ble_gatts_attr_md_t * p_md);

This can be useful in several scenarios, one of which is calculating or verifying the structure of the local Attribute Table regardless of the current attribute values, focusing instead only in the layout itself

GATT Server user memory layout for system attributes

The data format used by the GATT Server to store system attribute data is now fully documented in the API documentation for applications that need to parse it. The data format is used by the following 2 functions:

- sd_ble_gatts_sys_attr_set()
- sd_ble_gatts_sys_attr_get()

The format documentation applies to the data pointed to by the p_sys_attr_data pointer in both of the functions above.
